**Introduction**

The growth in the number of connected device usage has led to a rapidly increased data traffic on wireless network and the demand for access to high speed and stable Internet connection is becoming more prominent. However, current off the shelf wireless cards are not programmable or observable across layers of the standard protocol stack, which leads to poor practical performance.

**Object**

Implement and improve an 802.11 protocol, which is a Wifi style protocol, on fully programmable wireless radios.

**Methods**

**Wireless Open Access Research Platform (WARP) V3** [1] is a scalable wireless platform providing programmable functionality at every layer of the network stack.

![WARP node](image1)

**Data Flow** [1][3]

1. Samples to be transmitted are created in MATLAB as part of the custom PHY.
2. MATLAB downloads the samples to buffers on the transmitting WARP node.
3. MATLAB sends a trigger to transmitter and receiver nodes.
4. The transmitter node flushes its buffers through its radios while the receiver node loads its buffers with received data through its radios.
5. The received data is processed offline in MATLAB.

**Results**

**SISO OFDM (Serial Input Serial Output)**

Using 1 antenna at each transmitter and receiver.

![Figure 2 Plots with SISO OFDM](image2)

**MIMO OFDM (Multiple Input Multiple Output)**

Using 2 antennas at a transmitter to send two separate data streams and 2 antennas at the receiver to disentangle them.

![Figure 3 Plots with MIMO OFDM](image3)

**Conclusions**

In the project, MATLAB is used to control WARP nodes and perform signal processing. However, the previous results confirm that OFDM transmission and reception are done offline in MATLAB, which takes ~6sec.

Using spatial multiplexing technique, MIMO delivers higher data rate by transmitting multiple data streams simultaneously. Also, SISO has an increasing phase error per OFDM symbol while MIMO’s is decreasing by using space time block coding technique.

**Future Work**

In the future, the communication time should be reduced for real-time implementation. Additionally, any type of data (e.g. video streams) should be able to be transmitted and received through the WARP nodes.
