The existence of the dielectric constant $\varepsilon$ is investigated for fluid mixtures of rigid polar molecules. The investigation is performed using the functional-derivative formalism for mixtures, and is closely analogous to that previously carried out for pure dipolar fluids [J. Chem. Phys. 68, 5199 (1978)]. Sufficient conditions for the existence of $\varepsilon$ are obtained in terms of the direct correlation function matrix $c_{\alpha\beta}(12)$. It is found that $\varepsilon$ exists if $c_{\alpha\beta}(12)$ depends only on relative positions and orientations, and becomes asymptotic to $-\delta_{\alpha\beta}(12)/kT$ at long range, where $\delta_{\alpha\beta}(12)$ is the dipole-dipole potential between a molecule of species $\alpha$ and one of species $\beta$. An expression for $\varepsilon$ in terms of the short-range total correlation function matrix emerges automatically from the development. This expression is equivalent to an earlier result obtained by a different method. Expressions for $\varepsilon$ in terms of $c_{\alpha\beta}(12)$ are derived for axially symmetric molecules and for molecules of arbitrary symmetry. In the former case, the expression involves the inverse of an $N_{c} \times N_{c}$ matrix, where $N_{c}$ is the number of components in the mixture. This expression facilitates the evaluation of $\varepsilon$ in the mean spherical approximation. For molecules of arbitrary symmetry, the expression for $\varepsilon$ in terms of $c_{\alpha\beta}(12)$ involves the inverse of an $N_{c} \times N_{c}$ supermatrix, each element of which is a $3 \times 3$ matrix.

I. INTRODUCTION AND SUMMARY

The purpose of this article is to establish sufficient conditions for the existence of the dielectric constant $\varepsilon$ in dipolar fluid mixtures, and to examine the form of $\varepsilon$ in such mixtures in somewhat greater detail than has previously been done. Our development constitutes the extension to mixtures of previous work on pure dipolar fluids. As before, we restrict attention to rigid (un-polarizable) polar molecules.

The development is based on the functional-derivative formalism for fluid mixtures, and is closely analogous to that previously carried out for pure dipolar fluids. The functional-derivative formalism leads naturally to the introduction of the direct correlation function matrix $c_{\alpha\beta}(ab)$, in terms of which sufficient conditions for the existence of $\varepsilon$ can be simply expressed. It is found that $\varepsilon$ exists if $c_{\alpha\beta}(ab)$ is the sum of a short-range term that depends only on relative positions and orientations, and a long-range term $\delta_{\alpha\beta}(ab)/kT$, where $\delta_{\alpha\beta}(ab)$ is the dipole-dipole potential between a molecule of species $\alpha$ with coordinates $(a)$ and one of species $\beta$ with coordinates $(b)$. These conditions are straightforward mixture analogs of the sufficient conditions for the existence of $\varepsilon$ in pure dipolar fluids.

As in the single-component case, an expression for $\varepsilon$ emerges automatically as a by-product of the existence theorem. The structure of the present development is such that this expression involves a short-range total correlation function matrix $h_{\alpha\beta}(ab)$, rather than $c_{\alpha\beta}(ab)$. This expression is equivalent to an earlier result obtained, using an entirely different approach, by Martina and Deutch and by Høye and Stell.

We also derive expressions for $\varepsilon$ in terms of $c_{\alpha\beta}(ab)$, first for axially symmetric molecules and then for molecules of arbitrary symmetry. In the former case, the expression involves the inverse of an $N_{c} \times N_{c}$ matrix, where $N_{c}$ is the number of components in the mixture. An equivalent expression is implicit in the work of Høye and Stell. [Note that $\tau_{ij}$ should be replaced by $(\tau^{-1})_{ij}$ in their Eq. (18).] This expression facilitates the evaluation of $\varepsilon$ in the mean spherical approximation, since it makes the explicit consideration of finite-volume effects unnecessary. We perform this evaluation in terms of the functions $c_{\alpha\beta}(r)$ and $c_{\alpha\beta}(r)$ used by Freasier, Hamer, and Isbister (FHI). The resulting expression for $\varepsilon$ agrees with that of FHI when allowance is made for an error in their finite-volume correction.

Our expression for $\varepsilon$ in terms of $c_{\alpha\beta}(ab)$ for molecules of arbitrary symmetry has not previously been presented, although Høye and Stell have indicated how this expression could be derived within the framework of their formalism. This expression involves the inverse of an $N_{c} \times N_{c}$ supermatrix, each element of which is a $3 \times 3$ matrix. The expressions for $\varepsilon$ in terms of $c_{\alpha\beta}(ab)$ are more complicated than the expression involving $h_{\alpha\beta}(ab)$ because of the matrix inversions, but they have the advantage of being more easily evaluated in certain special cases, such as the mean spherical approximations.

II. EXISTENCE OF $\varepsilon$

In this section we establish sufficient conditions for the existence of $\varepsilon$ in terms of the behavior of $c_{\alpha\beta}(ab)$.
In the process, we automatically obtain an expression for $\epsilon$ in terms of $h_{ab}(ab)$.

We consider a finite volume $V$, of arbitrary shape, containing an arbitrary mixture of rigid (unpolarizable) polar molecules at constant temperature $T$. The number of components in the mixture is $N_c$, and the number of molecules of component or species $\alpha$ is $N_\alpha$. The number density of species $\alpha$ is $\rho_\alpha = N_\alpha / V$. The molecules of each species are of arbitrary symmetry.

The position and orientation of the $k$th molecule of species $\alpha$ are denoted by $r_{ak}$ and $\omega_{ak}$, respectively, and are collectively represented by the shorthand notation $(ak)$. Similarly, dummy coordinates $(r_a, \omega_a)$ are represented by $(a)$, $(r_b, \omega_b)$ by $(b)$, and so on. The angular measure $d\omega_a$ is denoted by $\Omega$.

To each molecule is rigidly affixed a coordinate frame which translates and rotates along with the molecule. These molecular coordinate frames are defined in the same way for all molecules of a given species, so that two such molecules coincide if their coordinate frames coincide. A molecular orientation $\omega$ is then defined by any convenient set of coordinates which specifies the orientation of the molecular frame with respect to the laboratory frame. If these coordinates are taken to be the Euler angles, $^6$ then $\omega = (\theta, \phi, \chi)$ and $\Omega = \delta \Sigma^3$. In the special case of axially symmetric molecules, the angle $\chi$ is irrelevant and we may take $\omega = (\theta, \phi)$, which makes $\Omega = 4\pi$.

Let $e_\omega = e^\prime(\omega)$, where $e^\prime(\omega)$ is the unit vector along the $p$ axis ($(p = 1, 2, 3$ or $x, y, z)$) of a coordinate frame with orientation $\omega$. The dipole moment vector of a molecule of species $\alpha$ with orientation $\omega_\alpha$ can then be written as

$$\mu_{\alpha} = \sum_p \mu^p_{\alpha} e^p_{\omega_\alpha},$$

(1)

where $\mu^p_{\alpha}$ is the component of the dipole moment of a molecule of species $\alpha$ along the $p$ axis in the molecular frame. The magnitude of the molecular dipole moment for species $\alpha$ is

$$\mu_{\alpha} = \left[ \sum_p (\mu^p_{\alpha})^2 \right]^{1/2}.$$

(2)

Our development is based upon the functional-derivative relations for fluid mixtures, which we now proceed to summarize. These relations are straightforward generalizations of those for pure fluids. $^7$ We are concerned here only with linear dielectric polarization, so we shall require these relations only in their zero-field limiting forms. This means that we may use the grand canonical relations even though we are in the canonical ensemble, provided that the $1/N$ correction terms in the total correlation functions are discarded. $^8, 9$

Suppose that the sample is subjected to external fields which add a term

$$\sum_{ab} \phi(a,b)$$

to the total potential energy of the system. The linear (first-order) deviation $\delta n_\alpha(a)$ of the single-molecule generic distribution function for species $\alpha$ from its zero-field value of $\rho_\alpha / \Omega$ is then given by

$$\delta n_\alpha(a) = -\beta_T \rho_\alpha \sum_b \int d(b) \phi(a,b) [n_b h_{ab}(ab) + \delta_{ab} \delta(ab) \omega] ,$$

(3)

where $\beta_T = 1/kT$, $n_a = \rho_a / \Omega$, $\delta_{ab}$ is the Kronecker delta, $\delta(ab)$ is the Dirac delta function in positions and orientations, and $h_{ab}(ab)$ is the total correlation function matrix in zero applied field. The inverse of this relation is

$$-\beta_T \phi_\alpha(a) = \sum_b \int d(b) \delta n_\alpha(b) [(c_{ab}(ab)) + n^2 \delta_{ab} \delta(ab)] ,$$

(4)

where $c_{ab}(ab)$ is the direct correlation function matrix in zero applied field. It follows from Eqs. (3) and (4) that $h_{ab}$ and $c_{ab}$ are related by the Ornstein-Zernike equation for mixtures,

$$h_{ab}(ab) = c_{ab}(ab) + \sum_{\alpha} \int d\omega \delta n_\alpha(a) \mu_{\alpha}.$$  

(5)

We now specialize to the case of dielectric polarization, in which the only external field present is an external electric field $E_0(r)$. The latter is arbitrary except for two restrictions: it must be weak enough that the sample responds to it linearly, and it must vary slowly (in a molecular sense) with the position $r$. The external potential functions $\phi_\alpha(a)$ now become

$$\phi_\alpha(a) = -\mu_{\alpha} \cdot E_0(r).$$

(6)

The dielectric behavior of the sample is determined by the polarization (induced dipole moment per unit volume) $P(r)$, which is related to $\delta n_\alpha(a)$ by

$$P(r) = \sum_a \int d\omega \delta n_\alpha(a) \mu_{\alpha}.$$

(7)

Sufficient conditions for the existence of $\epsilon$ are most easily expressed in terms of the direct correlation function matrix $c_{ab}(ab)$. We adopt two fundamental assumptions about its behavior:

(i) We assume that at long range (large $|r_a - r_b|$), $c_{ab}(ab)$ becomes asymptotic to $-\beta_T$ times the dipole-dipole potential between a molecule of species $\alpha$ with coordinates $(a)$ and one of species $\beta$ with coordinates $(b)$. That is,

$$c_{ab}(ab) = c_{ab}^0(ab) - \beta_T \theta_{ab}(ab),$$

(8)

$$\theta_{ab}(ab) = -\mu_{\alpha} \cdot T_\beta(r_a - r_b) \cdot \mu_{\beta},$$

(9)

$$T_\beta(r) = H(|r| - \sigma) \nabla \nabla |r|^{-1},$$

(10)

where $c_{ab}^0(ab)$ is a short-ranged function, $H(x)$ is the Heaviside unit step function, and it is understood that the limit $\sigma \rightarrow 0$ is ultimately to be taken.

(ii) We assume that $c_{ab}^0(ab)$ depends only on relative positions and orientations.

These assumptions are entirely analogous to those which imply the existence of $\epsilon$ in pure dipolar fluids. $^1$ In an infinite system, the validity of (i) may be inferred from the work of H"uygen and Stell, $^5$ and that of (ii) is a trivial consequence of translational and rotational invariance. In the finite systems of present concern, the validity of (i) and (ii) is very plausible (except of course in a negligibly thin surface layer, where (ii) will break down) but as yet unproved, and we shall not pursue the...
We have therefore shown that assumptions (i) and (ii) do indeed imply the existence of $\epsilon$ in dipolar fluid mixtures. Combining Eqs. (4), (6), and (8), we obtain

$$\beta_\Gamma \mu_{aa} \cdot E_L(r_2) = \sum_{ab} \int d(b) \, \delta_\alpha(b) \left[ -c_{aa}^0(ab) + n_a^0 \delta_{ab} \delta(b) \right] ,$$

(11)

where

$$E_L(r) = E_\alpha(r) + \int d(r') \, T_\alpha(r - r') \cdot P(r')$$

(12)

is the Lorentz electric field, which is related to the Maxwell electric field $E(r)$ by $E_L(r) = E(r) + (4\pi/3) P(r)$. In order to invert Eq. (11), we introduce a short-ranged total correlation function matrix $h_{aa}^0(ab)$ defined by

$$h_{aa}^0(ab) = c_{aa}^0(ab) + \sum_\alpha \int d(\alpha) \, h_{aa}^0(\alpha \alpha) \, c_{\alpha \alpha}(eb) ,$$

(13)

This definition enables Eq. (11) to be solved for $\delta_\alpha(a)$, with the result

$$\delta_\alpha(a) = \beta_\Gamma n_a \sum_\alpha \int d(b) \left[ n_\alpha h_{aa}^0(ab) + \delta_{ab} \delta(b) \right] \mu_{ab} \cdot E_L(r_2) .$$

(14)

Since $c_{aa}^0(ab)$ is short ranged, so is $h_{aa}^0(ab)$. The spatial integrals over $r_2$ in Eqs. (11) and (14) may therefore be extended over all space instead of just over the volume $V$, provided that $r_2$ is farther than the range of $c_{aa}^0(ab)$ or $h_{aa}^0(ab)$ from the surface of $V$. The integral over $r_2$ in Eq. (13) may similarly be extended over all space. In contrast, Eqs. (3), (4), and (5) involve the long-ranged functions $c_{aa}(ab)$ and $h_{aa}(ab)$, and the spatial integrals in these equations extend only over the sample volume $V$.

Since $E_\alpha(r)$ is slowly varying and the system is a fluid, it is clear that $P(r)$ and hence $E_L(r)$ will also be slowly varying. Combined with the fact that $h_{aa}^0(ab)$ is short ranged, this means that $E_L(r_2)$ in Eq. (14) may be evaluated at the point $r_2 = r_1$ and taken outside the integral over $b$. When this is done, the result combines with Eq. (7) to yield

$$P(r_2) = A(r_2) \cdot E_L(r_2) ,$$

(15)

where

$$A(r_2) = \beta_\Gamma \mu_{aa} \sum_\alpha \int d(r_2) \, d(\omega) \, d(\omega) \left[ n_\alpha h_{aa}^0(ab) + \delta_{ab} \delta(b) \right] \mu_{ab} \cdot E_L(r_2) .$$

(16)

But since $c_{aa}^0(ab)$ depends only on relative positions and orientations according to (ii), it is clear from Eq. (13) that the same is true for $h_{aa}^0(ab)$. By symmetry, therefore, $A(r_2)$ must be independent of $r_2$ and proportional to the unit tensor $I$. Thus $A(r_2) = A I$ and $A = (1/3) A I$. Equation (15) now reduces to $P(r) = A E_L(r)$, which shows 10 that the dielectric constant exists and is given by $(\epsilon - 1)/(\epsilon + 2) = 4\pi A/3$; i.e.,

$$\epsilon - 1 = 4\pi \beta_\Gamma \sum_\alpha \int d(r_2) \, d(\omega) \, d(\omega) \left[ n_\alpha h_{aa}^0(ab) + \delta_{ab} \delta(b) \right] \mu_{ab} \cdot \mu_{ab} .$$

(17)

We have therefore shown that assumptions (i) and (ii) imply the existence of $\epsilon$ in dipolar fluid mixtures, with $\epsilon$ given by Eq. (17). This expression for $\epsilon$ is equivalent to that obtained by Martina and Deutch$^3$ and Høye and Steil$^4$ using an entirely different method. [These authors' $W_{aa}(ab)$ is the same as our $\rho_a \rho_b h_{aa}^0(ab)$.]

### III. $\epsilon$ IN TERMS OF $c_{aa}(ab)$ FOR MOLECULES OF AXIAL SYMMETRY

In this section we derive the expression for $\epsilon$ in terms of $c_{aa}(ab)$ for axially symmetric molecules. To this end, we define

$$m_{a} = \frac{n_{\alpha}^{1/2}}{\mu_{\alpha}} ,$$

(18)

$$H_{aa} = \frac{(n_{\alpha} n_{\beta})^{1/2}}{\Omega_{\alpha} \mu_{\beta}} \int d(x) \, d(\omega) \, d(\omega) \, h_{aa}^0(ab) \mu_{a} \cdot \mu_{b} .$$

(19)

Equation (17) can now be rewritten as

$$\epsilon = \frac{4\pi}{9} \beta_\Gamma \sum_\alpha m_{a} \left[ \delta_{a\beta} + H_{aa} \right] m_{\beta} = \frac{4\pi}{9} \beta_\Gamma \Omega \left[ \hat{m}_{\gamma}^T (\hat{I} + \hat{H}) \hat{m}_{\gamma} \right] ,$$

(20)

where $\hat{m}$ is the $N_v$-dimensional column vector with elements $m_{a}$, $\hat{m}_{\gamma}$ is the corresponding row vector, $\hat{I}$ is the $N_v \times N_v$ unit matrix with elements $\delta_{a\beta}$, and $\hat{H}$ is the $N_v \times N_v$ matrix with elements $H_{aa}$. Multiply Eq. (13) by $(\Omega_{\alpha} \mu_{\beta})^{-1} (n_{\alpha} n_{\beta})^{1/2} \mu_{a} \cdot \mu_{b}$ and integrate over $r_2$, $\omega_a$, and $\omega_b$. The result is

$$H_{aa} = C_{aa} + \frac{(n_{\alpha} n_{\beta})^{1/2}}{\Omega_{\alpha} \mu_{\beta}} \int d(x) \, d(\omega) \, d(\omega) \, c_{aa}^0(ab) \mu_{a} \cdot \mu_{b} .$$

(21)

where

$$C_{aa} = \frac{(n_{\alpha} n_{\beta})^{1/2}}{\Omega_{\alpha} \mu_{\beta}} \int d(x) \, d(\omega) \, d(\omega) \, c_{aa}^0(ab) \mu_{a} \cdot \mu_{b} .$$

(22)

We note that $c_{aa}^0(ab)$ may be replaced by $c_{aa}(ab)$ in Eq. (22) without changing $C_{aa}$, so we can equally well write

$$C_{aa} = \frac{(n_{\alpha} n_{\beta})^{1/2}}{\Omega_{\alpha} \mu_{\beta}} \int d(x) \, d(\omega) \, d(\omega) \, c_{aa}(ab) \mu_{a} \cdot \mu_{b} .$$

(23)

The proof that this replacement is legitimate will be omitted, as it is entirely analogous to that of the corresponding property for pure dipolar fluids.  

The axial molecular symmetry, together with (ii), implies that $\int d(b) \, c_{aa}^0(eb) \mu_{b} = D_{a\beta} \mu_{a} \mu_{\gamma}$, where $D_{a\beta}$ is a constant independent of $\epsilon$. Its value may be determined by taking the dot product with $\mu_{a} \mu_{\gamma}$, integrating over $\omega_a$ for good measure. One thereby finds $D_{a\beta} = (n_{\alpha} n_{\beta})^{1/2} \times (\frac{\mu_{a} \mu_{\gamma}}{\mu_{a} \mu_{\gamma}}) C_{a\beta}$, so that

$$\int d(b) \, c_{aa}^0(eb) \mu_{b} = D_{a\beta} \mu_{a} \mu_{\gamma} .$$

(24)

With this result, Eq. (21) reduces to

$$H_{aa} = C_{aa} + \sum_{\gamma} H_{a\gamma} C_{\gamma\beta} ,$$

(25)

or in matrix notation

$$\hat{H} = \hat{C} + \hat{R} \hat{C} ,$$

(26)

where $\hat{C}$ is the $N_v \times N_v$ matrix with elements $C_{aa}$. It fol-
lows from Eq. (26) that \((\hat{I} + \hat{H}) = (\hat{I} - \hat{C})^{-1}\), which combines with Eq. (20) to yield
\[
\frac{\epsilon - 1}{\epsilon + 2} = \frac{4\pi}{9} \beta \Omega \left[ \tilde{m}^2 (\hat{I} - \hat{C})^{-1} \tilde{m} \right]
\]
Equation (27) is the expression for \(\epsilon\) in terms of \(c_{ab}(ab)\) for fluid mixtures of dipolar molecules with axial symmetry. An equivalent expression is implicit in the work of Høye and Stell.³

IV. \(\epsilon\) IN TERMS OF \(c_{ab}(ab)\) FOR MOLECULES OF ARBITRARY SYMMETRY

The development here follows the same outline as that of the preceding section, but is complicated by the fact that it is now necessary to resolve the dipole moment vectors into their components using Eq. (1). Let
\[
m_a^0 = n_a^{1/2} \mu_a^0, \quad H_{ab}^P = \Omega^{-1}(n_a n_b)^{1/2} \int d\omega_a d\omega_b \omega_a h_{ab}^0(\omega_a) \mathbf{e}_a^0 \cdot \mathbf{e}_b^0
\]
so that Eq. (17) can be rewritten in the form
\[
\frac{\epsilon - 1}{\epsilon + 2} = \frac{4\pi}{9} \beta \Omega \sum_{\alpha \neq \gamma} m_{\alpha}^0 (\delta_{\alpha \gamma} \delta_{\gamma \alpha} + H_{ab}^P) m_{\beta}^0
\]
\[
\frac{4\pi}{9} \beta \Omega \left[ \tilde{m}^2 (\hat{I} - \hat{C})^{-1} \tilde{m} \right].
\]
Here \(\tilde{m}\) is an \(N_c\) dimensional column supervector, whose \(\alpha\)th component is a 3-dimensional column vector with components \(m_{\alpha}^0\); \(\tilde{m}^2\) is the corresponding row supervector; \(\hat{H}\) is an \(N_c \times N_c\) supermatrix whose \(ab\) element is the \(3 \times 3\) matrix with elements \(H_{ab}^P\) and \(\hat{I}\) is the unit \(N_c \times N_c\) supermatrix, whose \(ab\) element is the \(3 \times 3\) matrix with elements \(\delta_{\alpha \gamma} \delta_{\gamma \alpha}\). One readily verifies that the multiplication rules for such supervectors and supermatrices are precisely those embodied in Eq. (30).

Now multiply Eq. (13) by \(\Omega^{-1}(n_a n_b)^{1/2} \mathbf{e}_a^0 \cdot \mathbf{e}_b^0\) and integrate over \(\omega_a\), \(\omega_b\), and \(\omega_s\) to obtain
\[
H_{ab}^P = C_{ab} + \Omega^{-1}(n_a n_b)^{1/2} \times \sum_{\gamma} n_\gamma \int d\omega_s d\nu d(\nu) h_{\alpha \nu}^0(\nu) c_{\nu \gamma}(\nu) \mathbf{e}_\gamma^0 \cdot \mathbf{e}_\gamma^0
\]
where
\[
C_{ab} = \Omega^{-1}(n_a n_b)^{1/2} \int d\omega_a d\omega_b d\omega_s h_{ab}(\omega_a) \mathbf{e}_a^0 \cdot \mathbf{e}_b^0
\]
The second equality in Eq. (32) expresses the fact that \(c_{\alpha \beta}(ab)\) may be replaced by \(c_{ab}(ab)\) without changing \(C_{ab}\); the proof is again analogous to that for pure dipolar fluids,¹ and hence is omitted. It should perhaps be noted that the analogous replacement of \(h_{ab}(\omega_a)\) by \(h_{ab}(\omega_a)\) in Eqs. (19) and (29) is not permissible.

Because of (ii), the quantity \(\int d\nu d(\nu) c_{\nu \gamma}(\nu) \mathbf{e}_\gamma^0\) must be a fixed vector in the molecular frame with orientation \(\omega_s\); it is therefore of the form \(\sum D_{ab}^r \mathbf{e}_b^0\), where \(D_{ab}^r\) are constants independent of \(e\). These constants may be determined by taking the dot product with \(\mathbf{e}_a^0\), and integrating over \(\omega_s\) for good measure. This yields \(D_{ab}^r = (n_a n_b)^{-1/2} \times C_{ab}^r\), so that
\[
\int d(\nu) c_{\nu \gamma}(\nu) \mathbf{e}_\gamma^0 = (n_a n_b)^{-1/2} \sum C_{ab}^r \mathbf{e}_b^0.
\]
This result now combines with Eq. (31) to give
\[
H_{ab}^P = C_{ab} + \Omega^{-1}(n_a n_b)^{1/2} \sum_{\alpha \neq \gamma} m_{\alpha}^0 (\delta_{\alpha \gamma} \delta_{\gamma \alpha} + H_{ab}^P) m_{\beta}^0
\]
or in supermatrix notation
\[
\hat{H} = \hat{C} + \hat{H}^P,
\]
where \(\hat{C}\) is the \(N_c \times N_c\) supermatrix whose \(ab\) element is the \(3 \times 3\) matrix with elements \(C_{ab}\). It follows from Eq. (35) that \(\hat{I} + \hat{H} = (\hat{I} - \hat{C})^{-1}\), whence Eq. (30) becomes
\[
\frac{\epsilon - 1}{\epsilon + 2} = \frac{4\pi}{9} \beta \Omega \left[ \tilde{m}^2 (\hat{I} - \hat{C})^{-1} \tilde{m} \right].
\]
Equation (36) is the expression for \(\epsilon\) in terms of \(c_{ab}(ab)\) for dipolar fluid mixtures with arbitrary molecular symmetry. This expression does not appear to have been previously presented, although Høye and Stell² have indicated how an equivalent expression could be derived in their theory.

V. THE MEAN SPHERICAL APPROXIMATION

In this section we show how the expression for \(\epsilon\) in terms of \(c_{ab}(ab)\) may be used to evaluate \(\epsilon\) in the mean spherical approximation (MSA) in terms of known functions. Since the MSA entails axial molecular symmetry, the appropriate equations are those of Sec. III.

The evaluation of \(\epsilon\) for dipolar mixtures in the MSA has recently been considered by Freasier, Hamer, and Isbister¹ (FHI). These authors performed the evaluation by generalizing Wertheim's procedure¹¹ to the case of mixtures. Unfortunately, this procedure involves a rather cumbersome finite-volume correction, which compensates for the fact that the system is finite rather than infinite. In the present development, however, no such correction is necessary; finite-volume effects are automatically accounted for by the fact that the spatial integral in the Ornstein–Zernike equation (5) extends only over the sample volume \(V\). We may therefore evaluate \(\epsilon\) simply by substituting the MSA expression for \(c_{ab}(ab)\) into Eq. (23) and combining the result with Eq. (27).
\[ \int d\omega \sum_{\sigma \sigma'} \mu_{\sigma \sigma'} = (\Omega/3) \mu_0 \mathbf{U}. \]

In terms of the conventional functions \( C_{a\beta}(r) \), Eq. (38) becomes

\[ C_{a\beta} = (8\pi/3) (\rho_a \rho_\beta)^{1/3} \int_0^\infty \frac{r^2 dr}{2} \left[ C_{a\beta}'(r) - C_{a\beta}(r) \right]. \quad (39) \]

The MSA result for \( \varepsilon \) is now determined by Eq. (27), with \( C_{a\beta} \) given by either Eq. (38) or Eq. (39).

We must now compare our MSA result for \( \varepsilon \) with that found by FHI. The FHI result is obtained by combining their Eqs. (2.60) and (2.62). Their quantities \( C_{a\beta}^{(k=0)} \) correspond to our quantities \( 4\pi \int r^2 dr C_{a\beta}(r) \). We note, however, that their Eq. (2.60) for the finite-volume correction is incorrect due to an error in transcription; the correct equation is obtained by replacing \( y'^{a\beta} \) with \(-y''_{a\beta}\). When this is done, it becomes a simple matter to verify that their result is precisely equivalent to our Eqs. (27) and (39). (Note that the result in this form is not restricted to binary mixtures.)

ACKNOWLEDGMENT

One of us (N.D.H.) would like to thank Professor S. H. Lin of Arizona State University for hospitality extended while this work was in progress.
