Introduction

The State of Oregon Department of Environmental Quality (DEQ) is developing a TMDL for temperature in the Willamette River basin shown in Figure 1. The study area included the Willamette River and all major tributaries (except the Tualatin River where a TMDL process was already concluded). A large section of the Columbia River was also modeled to provide adequate boundary representation of tidal flows in the lower Willamette River. The Willamette River below the Oregon City Falls in the Portland metropolitan area has a typical diurnal tidal range of 1 m. The development of a dynamic model of temperature and hydrodynamics of the entire river basin incorporating shading were primary requirements of this modeling study. The model would be used by DEQ to set temperature limits on point source dischargers and to evaluate the impact of management strategies on river temperatures to improve fish habitat. Some of these strategies included modifications of the dam at the Willamette River Falls south of Portland and channel reconfigurations.

![Figure 1: TMDL study area - the Willamette River basin with drainage basins delineated.](image)

CE-QUAL-W2 Version 3.1 (Cole and Wells, 2002), a two dimensional (longitudinal-vertical), laterally averaged, hydrodynamic and water quality model developed by the U.S. Army Corps of Engineers
(USACOE) Waterways Experiments Station, was chosen as the appropriate model tool for this system for the following reasons:

- Dynamic temperature predictive capability
- Dynamic shading prediction based on detailed topographic and vegetative shading information
- Ability of the model to be used for water quality after the temperature study where parameters of interest are algae, periphyton, pH, dissolved oxygen
- Ability to model complex hydraulic flow paths with multiple interconnected branches using hydraulic elements (weirs, pumps, spillways) between branches
- Ability to evaluate the stratification potential of deep pools in the Willamette River where water quality and temperature data have shown significant stratification
- Ability to model estuary hydrodynamics
- Ability to model an entire river basin including upstream deep-density stratified reservoirs
- Public domain executable and source code for quality-assurance and testing

The river basin model was originally divided into several reaches. Individual models were developed for each reach. These reaches were (see also Figure 2):

- **Columbia River** - from Beaver Army Terminal (Columbia River Mile 53.8) to Bonneville Dam (RM 144.5) (Willamette River enters the Columbia River at Columbia River Miles 87 and 101);
- **Tidal Willamette River** – Lower Willamette River from mouth to Willamette Falls (RM 26.5), including the Willamette Channel and the Multnomah Channel;
- **Non-tidal Willamette River** – Willamette Falls (RM 26.5) to confluence of Coast and Middle Forks (RM 187); this section was divided further into the following reaches: Middle Willamette from the Willamette Falls (RM 26.5) to the city of Salem (RM 85); Upper Willamette from the City of Salem (RM 85) to the confluence of Coast and Middle Forks (RM 187)
- **Clackamas River** up to River Mill Dam/Estacada Lake (RM 26);
- **Santiam River** (all 12 miles), North Santiam River up to Detroit Dam (RM 49), South Santiam River up to Foster Dam (RM 38);
- **Long Tom River** to Fern Ridge Dam (RM 26);
- **McKenzie River** to RM 56, and South Fork McKenzie River to Cougar Dam (RM 4);
- **Middle Fork Willamette** to Dexter Dam (RM 17), Fall Creek to Fall Creek Dam (RM 7);
- **Coast Fork Willamette** to Cottage Grove Dam (RM 30), Row River to Dorena Dam (RM 7.5);
- **Columbia Slough** in the tidal portion of the Willamette River (about 9 miles in length)

Once the models were set-up for each section of the Willamette basin, the model was calibrated to field data and management strategies were evaluated. These are the subjects of two other reports: Annear et al. (2004) and Berger et al. (2004).

This report outlines the results of implementing model scenarios for each of the model sections or elements for specific time periods. The model scenario simulation periods used to investigate management scenarios required boundary condition data that extended past the model calibration periods. The model simulation period for year 2001 was from June 1 to October 31 and for year 2002 from April 1 to October 31.
There were twenty one model scenarios run as shown in Table 1, based on a technical memo developed by the Oregon Department of Environmental Quality (ODEQ, 2003).

Model output results are presented in three output formats; time series plots of flow and temperature at specific site locations, longitudinal temperature plots for a specific data, contour plots of temperature difference over time and space comparing results between two model scenarios. The model output results are described in more detail:

1. Time series output at each location in Table 2
   - Hourly temperature and flows
   - Daily 7-day moving average of daily maximum temperature and 7-day average flow
Table 2: CE-QUAL-W2 Model Scenario output locations, based on ODEQ (2003).

Each model results section presents the figures with results from the furthest upstream reaches of the coast and Middle Forks of the Willamette River downstream to the Lower Willamette River with any modeled tributaries presented before each Willamette River Reach. The model reaches are presented in the following order:

- Coast/Middle Fork Willamette River
- McKenzie River
- Long Tom River
- Upper Willamette River
- Middle Willamette River
- Clackamas River
- Lower Willamette River
Time Series Comparisons

System Potential 1, 2001

System Potential 1 (ODEQ, 2003) was run for the summer of 2001 for three scenarios with varying discharges from the large point sources in the Willamette River system. The point sources were simulated as having no discharge, their current discharge in 2001, and their maximum permitted discharge. These results were then compared with the results of the calibrated model in a series of time series plots. There are four types of time series output for each of the 21 locations identified above in Table 2: continuous temperature, continuous flow, the seven-day moving average of the daily maximum temperature, and the seven-day average of daily average flow.

System Potential 1, 2002

System Potential 1 (ODEQ, 2003) was run for the summer of 2002 for three scenarios with varying discharges from the large point sources in the Willamette River system. The point sources were simulated as having no discharge, their current discharge in 2001, and their maximum permitted discharge. These results were then compared with the results of the calibrated model in a series of time series plots. There are four types of time series output for each of the 21 locations identified above in Table 2: continuous temperature, continuous flow, the seven-day moving average of the daily maximum temperature, and the seven-day average of daily average flow.

Continuous Temperature

System Potential 2, 2002

System Potential 2 (ODEQ, 2003) was run for the summer of 2002 for three scenarios with varying discharges from the large point sources in the Willamette River system. The point sources were simulated as having no discharge, their current discharge in 2001, and their maximum permitted discharge. These results were then compared with the results of the calibrated model in a series of time series plots. There are four types of time series output for each of the 21 locations identified above in Table 2: continuous temperature, continuous flow, the seven-day moving average of the daily maximum temperature, and the seven-day average of daily average flow.

Continuous Temperature

**Sensitivity to boundary flow rate**

The sensitivity of the model to upstream boundary flows was examined by simulating the summer of 2001 and adjusting the upstream boundary flows by +/- 20%. These results were then compared with the results of the calibrated model in a series of time series plots. There are four types of time series output for each of the 21 locations identified above in Table 2: continuous temperature, continuous flow, the seven-day moving average of the daily maximum temperature, and the seven-day average of daily average flow.

**Sensitivity to boundary temperature**

The sensitivity of the model to the upstream boundary temperature was examined by simulating the summer of 2001 and adjusting the upstream boundary temperatures by +/- 5ºC. These results were then compared with the results of the calibrated model in a series of time series plots. There are four types of time series output for each of the 21 locations identified above in Table 2: continuous temperature, continuous flow, the seven-day moving average of the daily maximum temperature, and the seven-day average of daily average flow.

**Continuous Temperature**

Sensitivity to vegetative shade

The sensitivity of the model to the varying vegetative shade was examined by simulating the summer of 2001 with no vegetative shade and System Potential vegetative shade. These results were then compared with the results of the calibrated model in a series of time series plots. There are four types of time series output for each of the 21 locations identified above in Table 2: continuous temperature, continuous flow, the seven-day moving average of the daily maximum temperature, and the seven-day average of daily average flow.

Continuous Temperature

**Sensitivity to biological opinion flows**

The sensitivity of the model to using the National Marine Fisheries Service Biological Opinion (NMFS BIOP) flows for the upstream boundary flow condition was examined by simulating the summer of 2001. The results were then compared with the results of the calibrated model in a series of time series plots. There are four types of time series output for each of the 21 locations identified above in Table 2: continuous temperature, continuous flow, the seven-day moving average of the daily maximum temperature, and the seven-day average of daily average flow.

**Continuous Temperature**

Longitudinal Profile Comparisons

*Sensitivity to Point Sources*

System Potential 1 (ODEQ, 2003) was run for the summer of 2001 for two scenarios with varying discharges from the large point sources in the Willamette River system. The point sources were simulated with no discharge and their maximum permitted discharge. These results were then compared in a series of longitudinal profiles for each river reach modeled. All of the longitudinal plots show the seven-day moving average of the daily maximum temperature for August 10, 2001 (ODEQ, 2003) and begin in the furthest upstream reaches of the watershed and move downstream.

Sensitivity to boundary flow rate

The sensitivity of the model to upstream boundary flows was examined by simulating the summer of 2001 and adjusting the upstream boundary flows by +/- 20%. These results were then compared with the results of the calibrated model in a series of longitudinal profiles for each river reach modeled. All of the longitudinal plots show the seven-day moving average of the daily maximum temperature for August 10, 2001 (ODEQ, 2003) and begin in the furthest upstream reaches of the watershed and move downstream.

Sensitivity to boundary temperature

The sensitivity of the model to the upstream boundary temperature was examined by simulating the summer of 2001 and adjusting the upstream boundary temperatures by +/- 5°C. These results were then compared with the results of the calibrated model in a series of longitudinal profiles for each river reach modeled. All of the longitudinal plots show the seven-day moving average of the daily maximum temperature for August 10, 2001 (ODEQ, 2003) and begin in the furthest upstream reaches of the watershed and move downstream.

**Sensitivity to biological opinion flows**

The sensitivity of the model to using the National Marine Fisheries Service Biological Opinion (NMFS BIOP) flows for the upstream boundary flow condition was examined by simulating the summer of 2001. These results were then compared with the results of the calibrated model in a series of longitudinal profiles for each river reach modeled. All of the longitudinal plots show the seven-day moving average of the daily maximum temperature for August 10, 2001 (ODEQ, 2003) and begin in the furthest upstream reaches of the watershed and move downstream.

Contour Plot Comparisons

The sensitivity of the model was tested by making specific changes to the model and comparing the results with the results from other scenarios. A comprehensive way to examine the model sensitivity is generate a contour plot of the difference between two model scenarios over an entire river reach and for the duration of the summer of 2001. The model scenario results were analyzed to generate the seven-day moving average of the daily maximum temperature for each model segment and for the whole simulation period. Then one model scenario temperature statistic was subtracted from another model scenario temperature statistic. The resulting change in temperature between the two scenarios (delta plot) was then plotted a contour plot with River mile along the x-axis and Julian day along the y-axis and color gradations representing the temperature differences between the two scenarios.

Sensitivity to point sources

System Potential 1 (ODEQ, 2003) was run for the summer of 2001 for two scenarios with varying discharges from the large point sources in the Willamette River system. The point sources were simulated with no discharge and their maximum permitted discharge. The difference between the seven-day moving average of the daily maximum temperature for each scenario was then taken and plotted as contour plot for each river reach modeled (ODEQ, 2003). The contour plots begin in the furthest upstream reaches of the watershed and move downstream. Since there were no point sources discharges simulated in the Long Tom River and Clackamas River model reaches the difference between the two scenarios would be zero so no contour plots were generated.

Figure 880: Maximum Permitted Point Sources vs. No Point Sources contour plot comparison, 7-day average of the daily maximum for August 10, 2001 for the Lower Willamette River
**Sensitivity to boundary flow rate reduction**

The sensitivity of the model to a 20% reduction in upstream boundary flows was examined by simulating the summer of 2001 and comparing it to the calibrated model. The difference between the seven-day moving average of the daily maximum temperature for each scenario was then taken and plotted as contour plot for each river reach modeled (ODEQ, 2003). The contour plots begin in the furthest upstream reaches of the watershed and move downstream.

Figure 888: Calibrated model vs. boundary flow reduction (-20%) contour plot comparison, 7-day average of the daily maximum for August 10, 2001 for the Lower Willamette River
Sensitivity to boundary flow rate increase

The sensitivity of the model to a 20% increase in upstream boundary flows was examined by simulating the summer of 2001 and comparing it to the calibrated model. The difference between the seven-day moving average of the daily maximum temperature for each scenario was then taken and plotted as contour plot for each river reach modeled (ODEQ, 2003). The contour plots begin in the furthest upstream reaches of the watershed and move downstream.

Sensitivity to boundary temperature reduction

The sensitivity of the model to a 5 °C reduction in the upstream boundary temperature was examined by simulating the summer of 2001 and comparing it to the calibrated model. The difference between the seven-day moving average of the daily maximum temperature for each scenario was then taken and plotted as contour plot for each river reach modeled (ODEQ, 2003). The contour plots begin in the furthest upstream reaches of the watershed and move downstream.

Sensitivity to boundary temperature increase

The sensitivity of the model to a 5 °C increase in the upstream boundary temperature was examined by simulating the summer of 2001 and comparing it to the calibrated model. The difference between the seven-day moving average of the daily maximum temperature for each scenario was then taken and plotted as contour plot for each river reach modeled (ODEQ, 2003). The contour plots begin in the furthest upstream reaches of the watershed and move downstream.

Sensitivity to vegetative shade

The sensitivity of the model to the varying vegetative shade was examined by simulating the summer of 2001 with no vegetative shade and System Potential vegetative shade. The difference between the seven-day moving average of the daily maximum temperature for each scenario was then taken and plotted as contour plot for each river reach modeled (ODEQ, 2003). The contour plots begin in the furthest upstream reaches of the watershed and move downstream.

Sensitivity to biological opinion flows

The sensitivity of the model to using the National Marine Fisheries Service Biological Opinion (NMFS BIOP) flows for the upstream boundary flow condition was examined by simulating the summer of 2001. These results were then compared with the results of the calibrated model. The difference between the seven-day moving average of the daily maximum temperature for each scenario was then taken and plotted as contour plot for each river reach modeled (ODEQ, 2003). The contour plots begin in the furthest upstream reaches of the watershed and move downstream. Since there were no NMFS Biological Opinion flows for the Clackamas River model reach the difference between the two scenarios would be zero so no contour plots were generated.
