# *Evolutionary Ideas in Computing*

# Theory of Evolution - Darwin

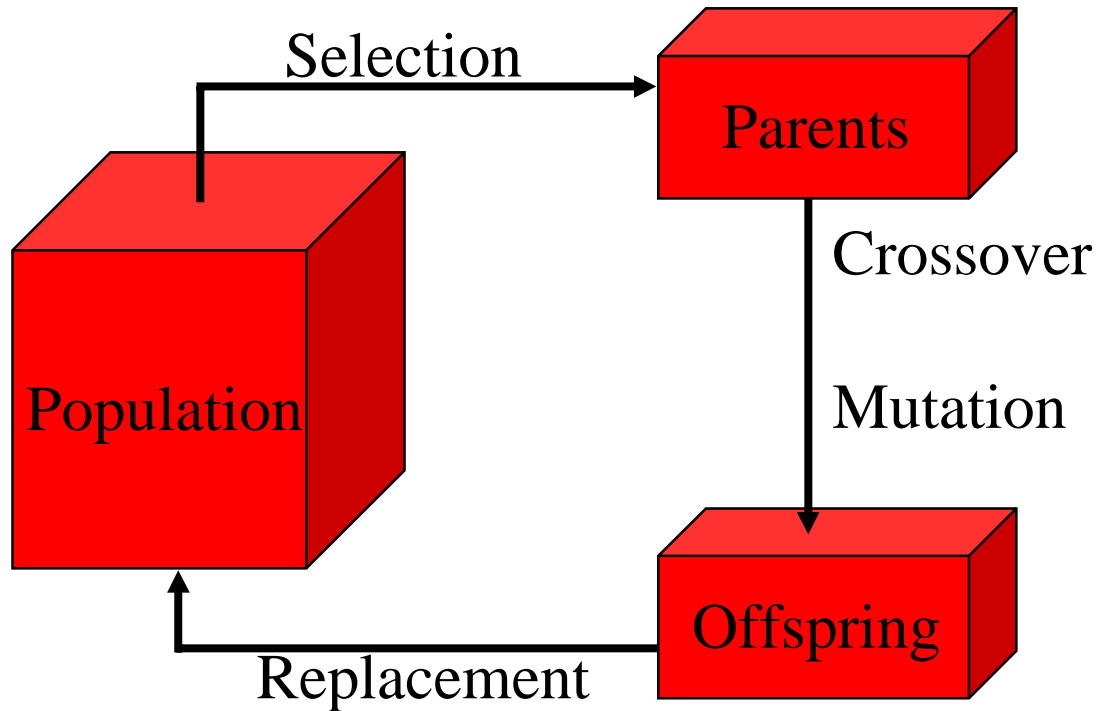

1859

**Charles Darwin  
(1809 - 1882)**

# General Principle

# Concepts from Genetics I

- A **gene** is a short length of a chromosome which controls a characteristic of an organism.
- The gene can be passed on from parent to offspring, e.g. a gene for eye-color.

## Concepts from Genetics II

- A chromosome is a chain of genes
- Each living object has a particular number of chromosomes, e.g. human beings have 46 chromosomes.

- Given a problem that in some way involves a search, a genetic algorithm begins with chromosome which represents a solution (usually a **binary** string).
- We will use **non-binary** strings also

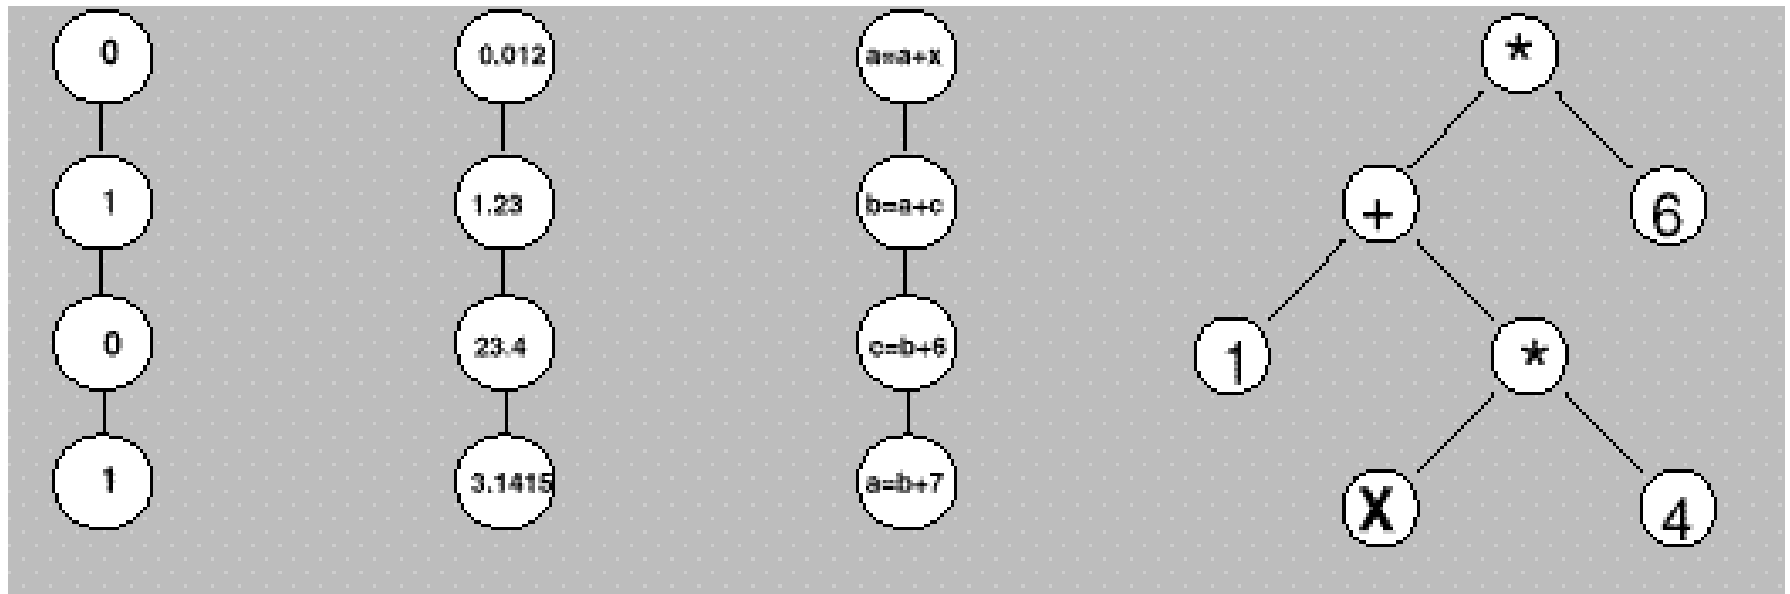

# GA Structure

**Human Chromosome**

**Linear collection of bits (GA Chromosome)**

# Representation of individuals in various EAs

# GA Components

- **Population** - consists of individuals who may be able to solve the given problem
- **Fitness function** – a function which determines how well each individual solves the problem

# Contents of the Three Lectures on Evolutionary Algorithms

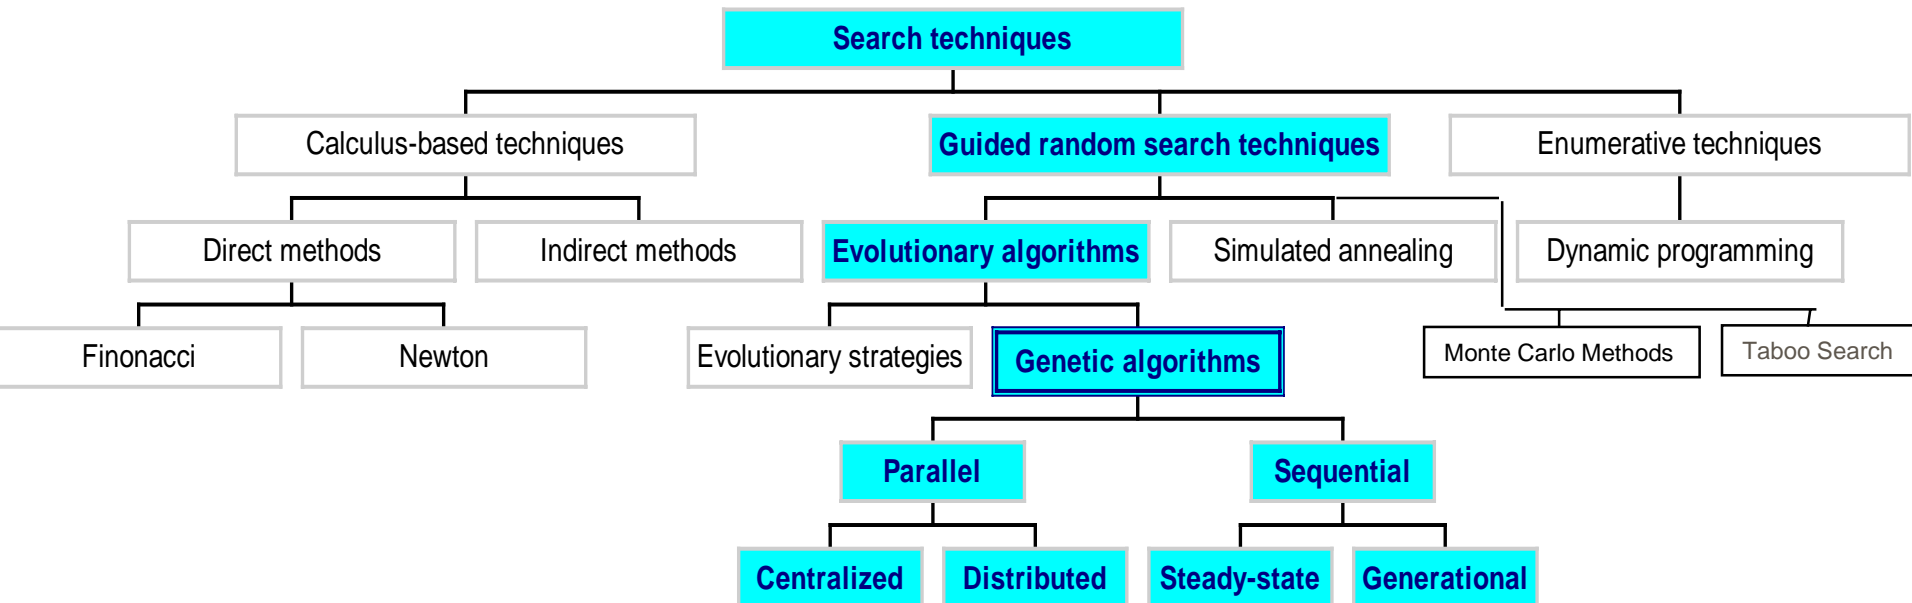

- Taxonomy and History;
- Evolutionary Algorithms basics;
- Theoretical Background;
- Outline of the various techniques: plain genetic algorithms, evolutionary programming, evolution strategies, genetic programming;
- **Practical** implementation issues;
- Evolutionary algorithms and **soft computing**;
- Selected applications;
- **Evolutionary Hardware**;
- Summary and Conclusions.

# Taxonomy of Evolutionary Algorithms (1)

Evolutionary computing is a family of stochastic search techniques that mimic the natural evolution.

# Taxonomy of Evolutionary Algorithms (1)

Evolutionary algorithms as a subdivision of soft computing:

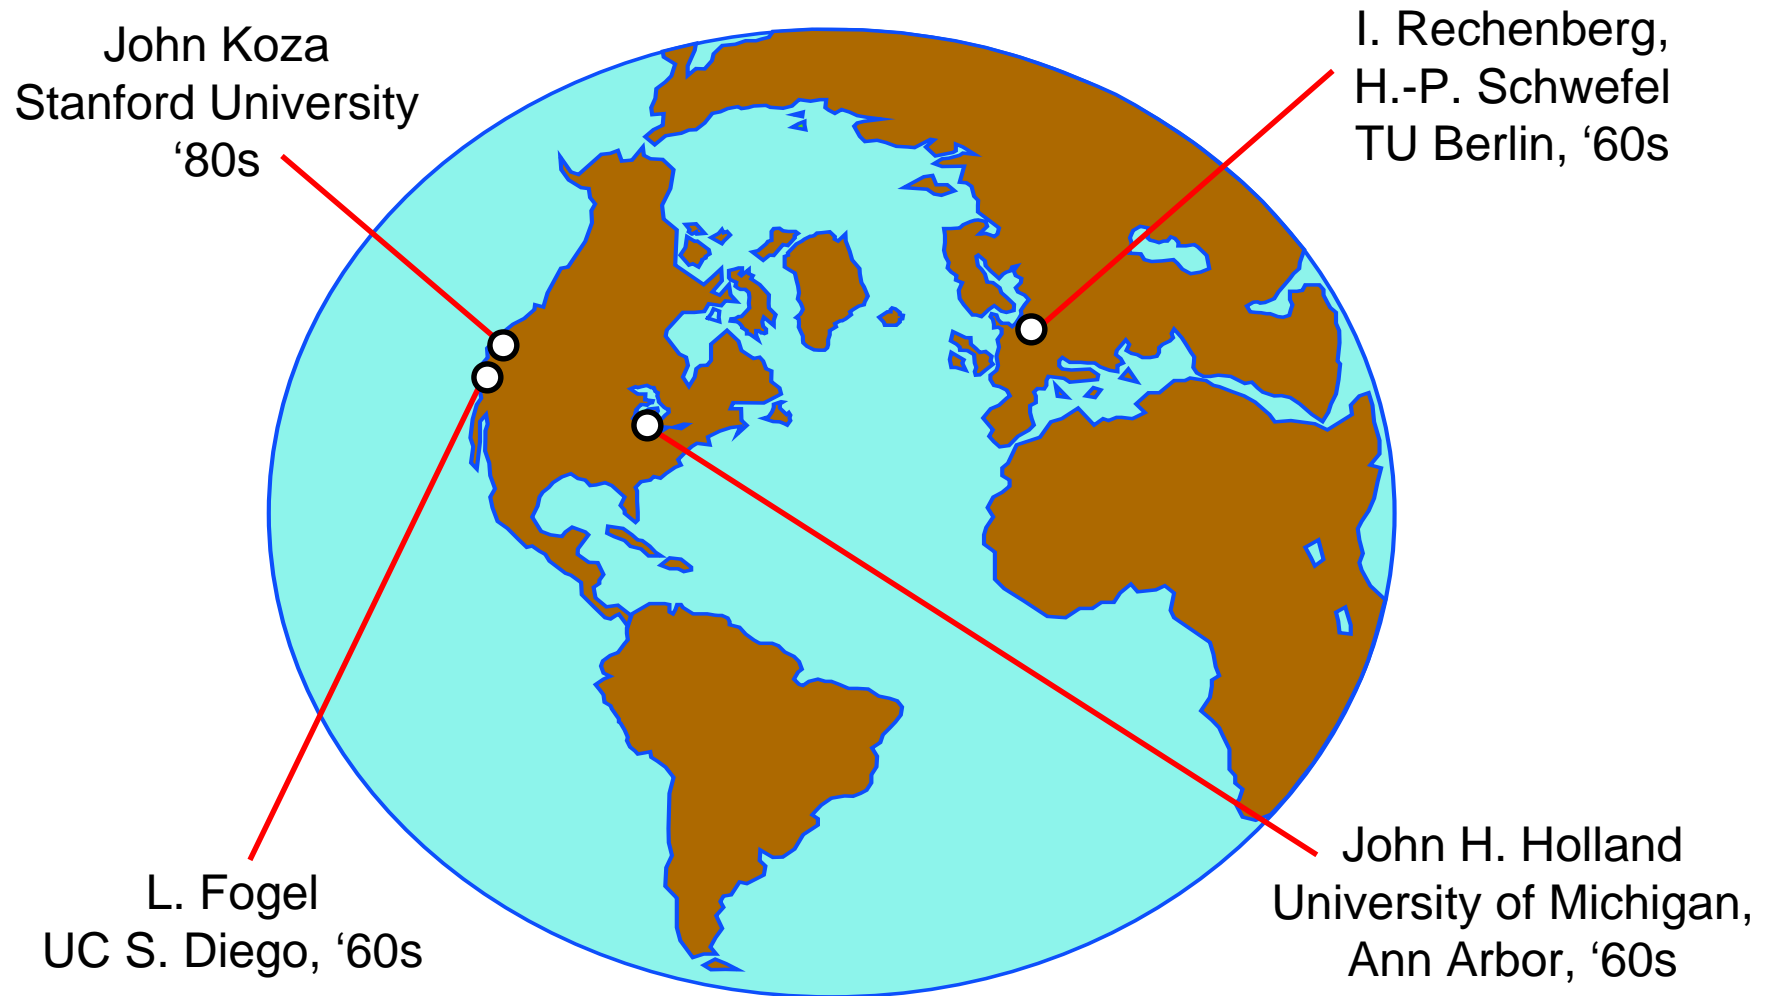

# Taxonomy of Evolutionary Algorithms (2)

## Distinctive Properties of Evolutionary Algorithms

- verification of correctness of solution ;
- consideration of instances in the population of candidate solutions ;
- deriving solutions from solutions ;
- Probabilistic transition rules

# Evolutionary Algorithms Basics

- what an EA is (the Metaphor)
- object problem and fitness
- the Ingredients
- schemata
- implicit parallelism
- the Schema Theorem
- the building blocks hypothesis
- deception

# A metaphore

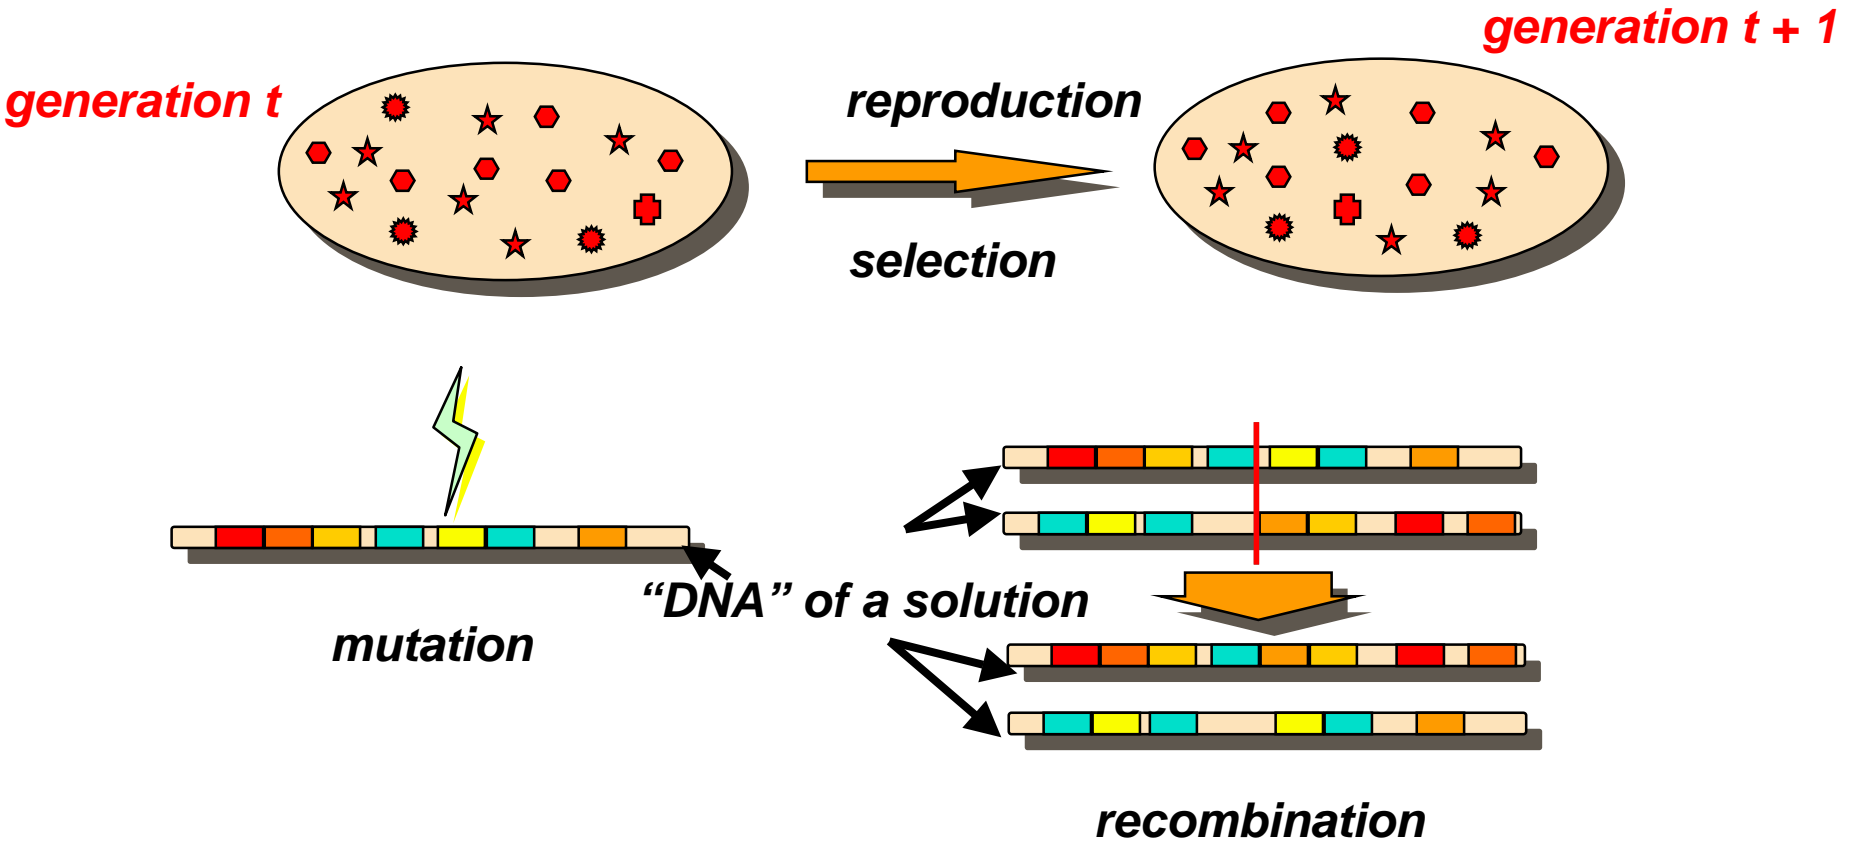

EVOLUTION	PROBLEM SOLVING
Environment	Problem to solve
Population	Set of alternative solutions
Generation	Iteration step
Individual	Candidate solution
Parents	Individuals chosen for reproduction
Adaptation measure	Fitness function
Genotype	String of characters
Phenotype	Decoded solution (circuit,plant)
Metagenesis	Process of transition from the current to the next generation

# Object problem and Fitness

# Ingredients of an evolutionary algorithm

## *Population of solutions*

# Let us go into more details.....

- EA Structure
- EA Operators
- EA Applications
- Specific types of Eas: GA, GP, ES...
- EA Examples

# EA Structure

# Example 1: Genetic Algorithm for MAXONE problem

- The MAXONE problem
- Genotypes are bit strings
- Fitness-proportionate selection
- One-point crossover
- Flip mutation (transcription error)

# The MAXONE Problem

**Problem instance:** a string of  $l$  binary cells,  $\gamma \in \{0, 1\}^l$ :

**Fitness:**

$$f(\gamma) = \sum_{i=1}^l \gamma_i$$

**Objective:** maximize the number of ones in the string.

# Genetic Algorithm Inspired by natural evolution

- **Population** of individuals
  - Individual is feasible solution to problem
- Each individual is characterized by a **Fitness function**
  - Higher fitness means a better solution
- Based on their fitness, parents are selected to reproduce **offspring** for a new **generation**
  - Fitter individuals have more chance to reproduce
  - New generation has same size as old generation; old generation dies
- Offspring has **combination** of properties of two parents
- If well designed, population will **converge** to optimal solution

# Evolutionary Computing

# Example 2: Discrete Representation of various type of data in Genetic Algorithms

- Genotype: 8 bits

1	0	1	0	0	0	1	1
---	---	---	---	---	---	---	---

- Phenotype:

- integer

$$1*2^7 + 0*2^6 + 1*2^5 + 0*2^4 + 0*2^3 + 0*2^2 + 1*2^1 + 1*2^0 = 163$$

- a real number between 2.5 and 20.5

$$2.5 + 163/256 (20.5 - 2.5) = 13.9609$$

- schedule

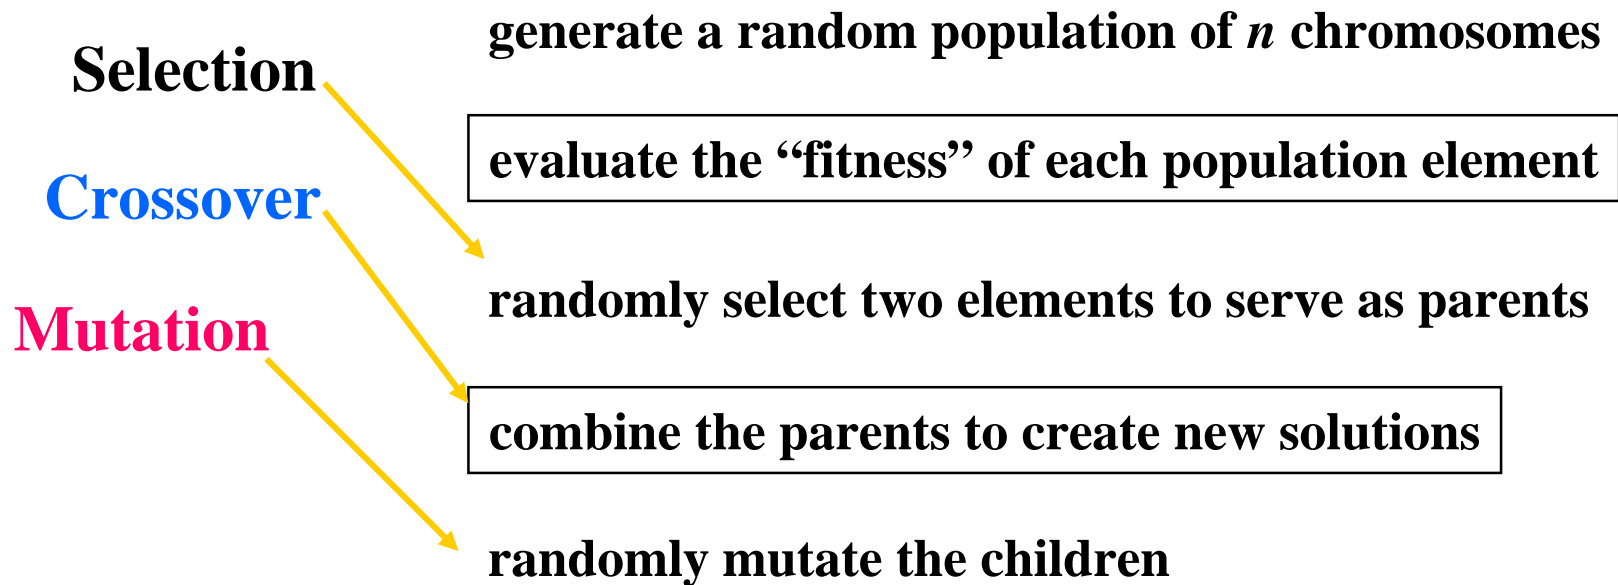

- GAs will cycle through populations of binary strings until a solution is found or a maximum number of generations have been created
- Various stopping criteria

# GA Process

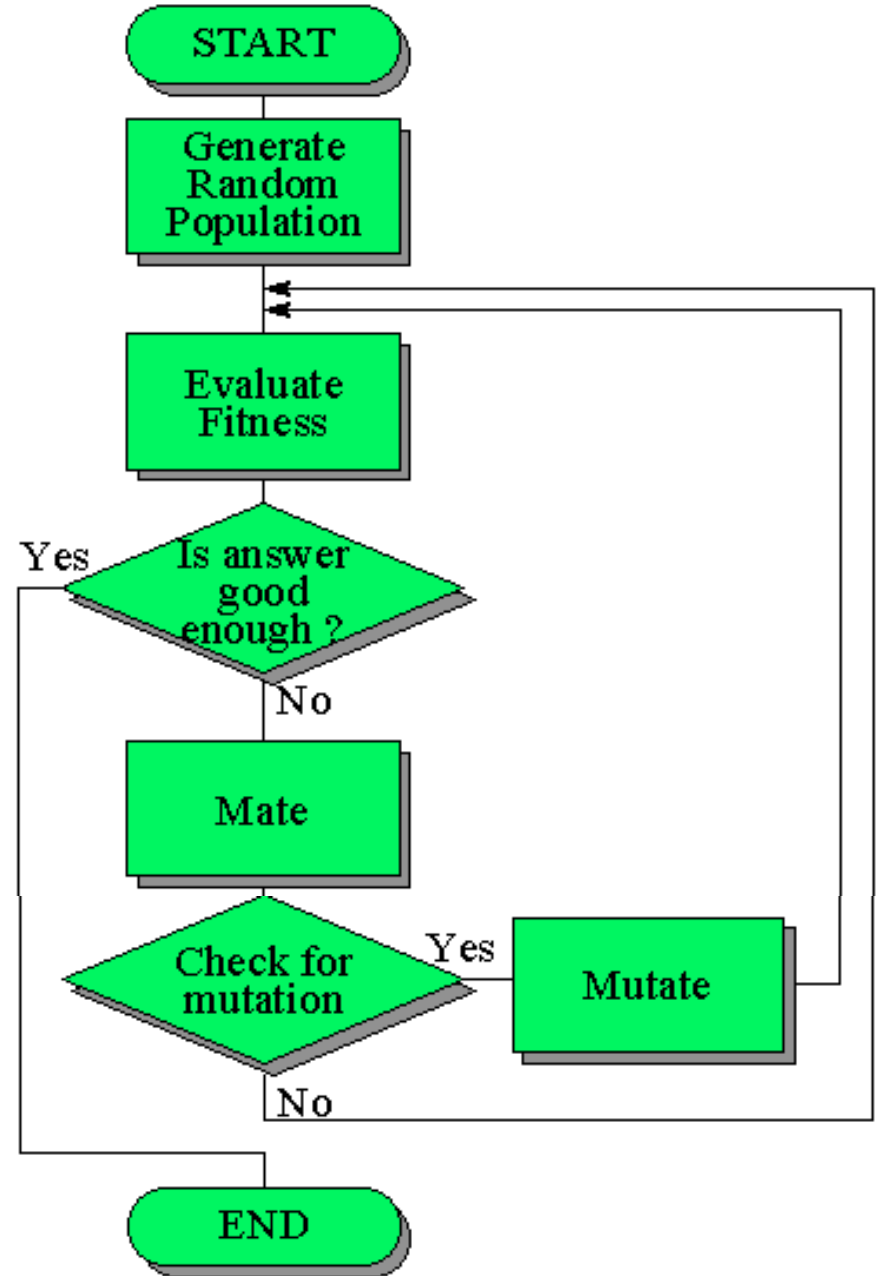

# GA Steps

- A GA will implement the following:

## GA FLOW CHART

# Pseudocode of EA

```
generation = 0;  
SeedPopulation(popSize); // at random or from a file  
while(!TerminationCondition())  
{  
    generation = generation + 1;  
    CalculateFitness(); // ... of new genotypes  
    Selection(); // select genotypes that will reproduce  
    Crossover( $p_{cross}$ ); // mate  $p_{cross}$  of them on average  
    Mutation( $p_{mut}$ ); // mutate all the offspring with Bernoulli  
                        // probability  $p_{mut}$  over genes  
}
```

# Pseudocode of EA (another variant)

BEGIN

Generate initial population;

Compute fitness of each individual;

REPEAT /\* New generation \*/

FOR population\_size / 2 DO

    Select two parents from old generation;

        /\* biased to the fitter ones \*/

    Recombine parents for two offspring;

    Compute fitness of offspring;

    Insert offspring in new generation

END FOR

UNTIL population has converged

END

# Example of convergence

Usefulness of analyzing such curves

# Link between GA and a Problem

- Reproduction mechanisms have no knowledge of the problem to be solved
- Link between genetic algorithm and problem:
  - Coding
  - Fitness function

# Basic principles: genotype and phenotype

- An individual is characterized by a set of parameters: **Genes**
- The genes are joined into a string: **Chromosome**
- The chromosome forms the **genotype**
- The **genotype** contains all information to construct an organism: the **phenotype**
- **Reproduction** is a “dumb” process on the chromosome of the **genotype**
- **Fitness** is measured in the real world (‘struggle for life’) of the **phenotype**

# Coding

- Design alternative → individual (chromosome)
- Single design choice → gene
- Design objectives → fitness

Each of us is a  
design alternative,  
thanks to our parents

***Chromosomes are strings of bits,  
symbols, lists of atoms, etc,***

# Coding

- Parameters of the solution (**genes**) are concatenated to form a string (**chromosome**)
- All kind of **alphabets** can be used for a chromosome (numbers, characters), but generally a **binary alphabet** is used
- **Order** of genes on chromosome can be important
- Generally many **different codings** for the parameters of a solution are possible
- **Good coding is probably the most important factor for the performance of a GA**
- In many cases many possible chromosomes do not encode feasible solutions

# Example of problem fomulation

- Problem
  - Schedule  $n$  jobs on  $m$  processors such that the maximum span is minimized.

**Design alternative:** job  $i$  ( $i=1,2,\dots,n$ ) is assigned to processor  $j$  ( $j=1,2,\dots,m$ )

**Individual:** A  $n$ -vector  $\mathbf{x}$  such that  $x_i = 1, \dots, \text{or } m$

**Design objective:** minimize the maximal span

**Fitness:** the maximal span for each processor

# Reproduction

- Reproduction operators
  - Crossover
  - Mutation

## Example

- Assume the parents selected are:

These are the two children which  
are now part of the **next generation**

Find a **random** crossover **point**

Swap the bits after the crossover point

# Crossover algorithm

- Select two random parents
- Using the preset probability of a crossover,  $p_c$ , throw a random number,  $r$ .
  - if  $r < p_c$  then perform a crossover operation on the two parents
  - otherwise pass both parents on to the next generation
- Repeat this process until the next generation is full
- Two parents produce two offspring
  - There is a chance that the chromosomes of the two parents are copied unmodified as offspring
  - There is a chance that the chromosomes of the two parents are randomly recombined (crossover) to form offspring
  - Generally the chance of crossover is between 0.6 and 1.0

# Recombination: genotype versus phenotype

- Each chromosome is cut into 2 pieces which are recombined

parents

offspring

# One-point crossover 1

- Randomly one position in the chromosomes is chosen
- Child 1 is head of chromosome of parent 1 with tail of chromosome of parent 2
- Child 2 is head of 2 with tail of 1

Randomly chosen position

Generating offspring from two selected parents

1. Single point crossover
2. Two point crossover (Multi point crossover)
3. Uniform crossover

# Crossover Operators comparison

- Single point crossover

- Two point crossover (Multi point crossover)

# One-point crossover - Nature

But we do not have to  
follow the Nature in EA

# Two-point crossover

- Randomly **two positions** in the chromosomes are chosen
- Avoids that genes at the head and genes at the tail of a chromosome are **always split** when recombined

Remember the elephants  
example?

# Uniform Crossover

- **PROCESS:**

- each bit in the **first offspring** is selected sequentially from parent 1 with **probability p** and from parent 2 with **probability (1-p)**,
- the **second offspring** receives the **bit not selected** for the first offspring.
- Probabilities of next bits can be constrained on previous values and choices

- **EXAMPLE:**

- $P(\text{parent1}) = 0.9$

- $P(\text{parent1}) = 0.3$

These choices correspond to create dynamically a mask for both parents

Parents:

Children:

# Uniform crossover (other variant)

- 1. A **random mask** is generated
- 2. The mask determines which bits are copied from one parent and which from the other parent
  - Bit density in mask determines how much material is taken from the other parent (takeover parameter)
- This mask may be biased - not totally random but user-influenced.

<b>Mask:</b>	0110011000	(Randomly generated)
<b>Parents:</b>	<u>1</u> 0 <u>1</u> 00 <u>0</u> 1110	<u>0</u> 0 <u>1</u> <u>1</u> 0 <u>1</u> 00 <u>1</u> 0
<b>Offspring:</b>	00 <u>1</u> 100 <u>1</u> 010	<u>1</u> 0100 <u>1</u> 0110

- Is uniform crossover better than single crossover point?
  - Trade off between
    - **Exploration:** introduction of new combination of features
    - **Exploitation:** keep the good features in the existing solution

# Problems with crossover

- Depending on coding, **simple crossovers** can have high chance to produce **illegal offspring**
  - E.g. in **TSP** with simple binary or path coding, most offspring will be illegal because not all cities will be in the offspring and some cities will be there more than once
- **Uniform crossover** can often be modified to avoid this problem
  - E.g. in TSP with simple path coding:
    - | Where mask is 1, copy cities from one parent
    - | Where mask is 0, choose the remaining cities in the order of the other parent

# *Mutation*

- Generating new offspring from single parent

- This operator helps maintaining the diversity of the individuals
  - | **Crossover** can only explore the combinations of the current gene pool
  - | **Mutation** can "generate" new genes

# *Mutation (cont)*

- As each chromosome is added to the next generation, it is examined bit by bit
  - each time a bit is examined, a random number is thrown,  $r$
  - if  $r < P_m$  then that bit is complemented otherwise it is left unchanged
- The whole cycle begins again - it will stop when either a solution is found or the maximum number of generations have been produced

There is a chance that a gene of a child is changed randomly  
Generally the chance of mutation is low (e.g. 0.001)

## Example: Binary Mutation

- A bit in a child is changed (from 1 to 0 or from 0 to 1) at random

This is a usually **small probability** event but in some approaches it may be quite high

The effect is to **prevent a premature convergence** to a local minimum or maximum

# Mutation

independent Bernoulli transcription errors

Sometimes there is high mutation rate and its probability is generated for each gene, dynamically with analyzing previous changes. Many bits can change in one generation.

## Example: Binary Mutation

before

1 1 1 1 1 1 1

after

1 1 1 0 1 1 1

mutated bit

Mutation happens with probability  $p_m$  for each bit

# Reproduction Operators

- **Control parameters:** population size, crossover/mutation probability
  - These parameters are problem specific
  - **P1.** Increase population size
    - | Increase diversity and computation time for each generation
  - **P2.** Increase crossover probability
    - | Increase the opportunity for recombination but also disruption of good combination
  - **P3.** Increase mutation probability
    - | Closer to randomly search
    - | Help to introduce new gene or reintroduce the lost gene
  - **P4.** Vary the population
    - | Usually using crossover operators to recombine the genes to generate the new population, then using mutation operators on the new population

# EA Performance: Diversity

- **Increasing** diversity by genetic operators
  - mutation
  - Recombination
- **Decreasing** diversity by selection
  - of parents
  - of survivors

# GA: crossover OR mutation?

If we define **distance** in the search space as Hamming distance then:

- Crossover is **explorative**, it **makes a big jump** to an area somewhere 'in between' two (parent) areas.
- Mutation is **exploitative**, it creates **random small variations**, thereby staying near the parent.
- To hit the optimum you often need a lucky mutation.
- **GA community**: crossover is mission critical.

# Genetic Algorithm for function optimization

Numerical Example:

$$F(x, y) = -x^2 - 2y^2 + \cos(3\pi x) + 0.3\cos(4\pi y) + 4$$
$$-1 \leq x \leq 1 \quad -1 \leq y \leq 1$$

# Genetic Algorithm for function optimization

$$s_i = \underbrace{[1 \ 0 \ 0 \ 1 \ 0 \ 1 \ 1 \ 1]}_x \underbrace{[0 \ 0 \ 1 \ 1 \ 1 \ 0 \ 1 \ 1]}_y$$

First Generation of 50

After 150 Generation

# Genetic Algorithm for function optimization

Evolution of average fitness

# Parent selection

- The process in which individual strings in the population are selected to contribute to the next generation is called **parent selection**
  - based on fitness
  - strings with a **high fitness** have a higher probability of contributing one or more offspring to the next generation
- **Example:** Biased **Roulette Wheel** Selection

**Specifically:** Fitness proportionate selection

- Expected number of times chromosome with  $f_i$  is selected equals  $f_i / \text{average fitness}$

When you spin the wheel, items 1 and 5 have the greatest chance of coming up while item 2 has the smallest

**Best  
individuals  
obtain this  
much**

**Worst**

# Fitness Proportionate Selection

Probability of  $\gamma$  being selected:

$$P(\gamma) = \frac{f(\gamma)}{\sum f}$$

**Implementation:** “Roulette Wheel”

# Example: Selection for MAXONE

Number of bits 1  
in the string

Cumulative f

Probability of  
being selected

0111011011	$f = 7$	$Cf = 7$	$P = 0.125$	● ●
1011011101	$f = 7$	$Cf = 14$	$P = 0.125$	
1101100010	$f = 5$	$Cf = 19$	$P = 0.089$	● ●
0100101100	$f = 4$	$Cf = 23$	$P = 0.071$	●
1100110011	$f = 6$	$Cf = 29$	$P = 0.107$	●
1111001000	$f = 5$	$Cf = 34$	$P = 0.089$	
0110001010	$f = 4$	$Cf = 38$	$P = 0.071$	● ●
1101011011	$f = 7$	$Cf = 45$	$P = 0.125$	● ●

<b>011000</b>   <b>1010</b>	→	<b>0110001011</b>	→	0110001011	f = 5
<b>110101</b>   <b>1011</b>	→	<b>1101011010</b>	→	1101011010	f = 6

TOTAL = 57

Total increased in  
next generation

# Parent selection: another Example

## Roulette wheel

- Sum the fitness of all chromosomes, call it T
- Generate a random number N between 1 and T
- Return chromosome whose fitness added to the running total is equal to or larger than N
- Chance to be selected is exactly proportional to fitness

Chromosome:	1	2	3	4	5	6
Fitness:	8	2	17	7	4	11
Running total:	8	10	27	34	38	49
N ( $1 \leq N \leq 49$ ):			23			
Selected:			3			

# Parent/Survivor Selection

- Strategies
  - Survivor selection:
    - | 1. Always keep the best one,
    - | 2. Elitist: deletion of the K worst
    - | 3. Probability selection: inverse to their fitness
    - | 4. Etc.

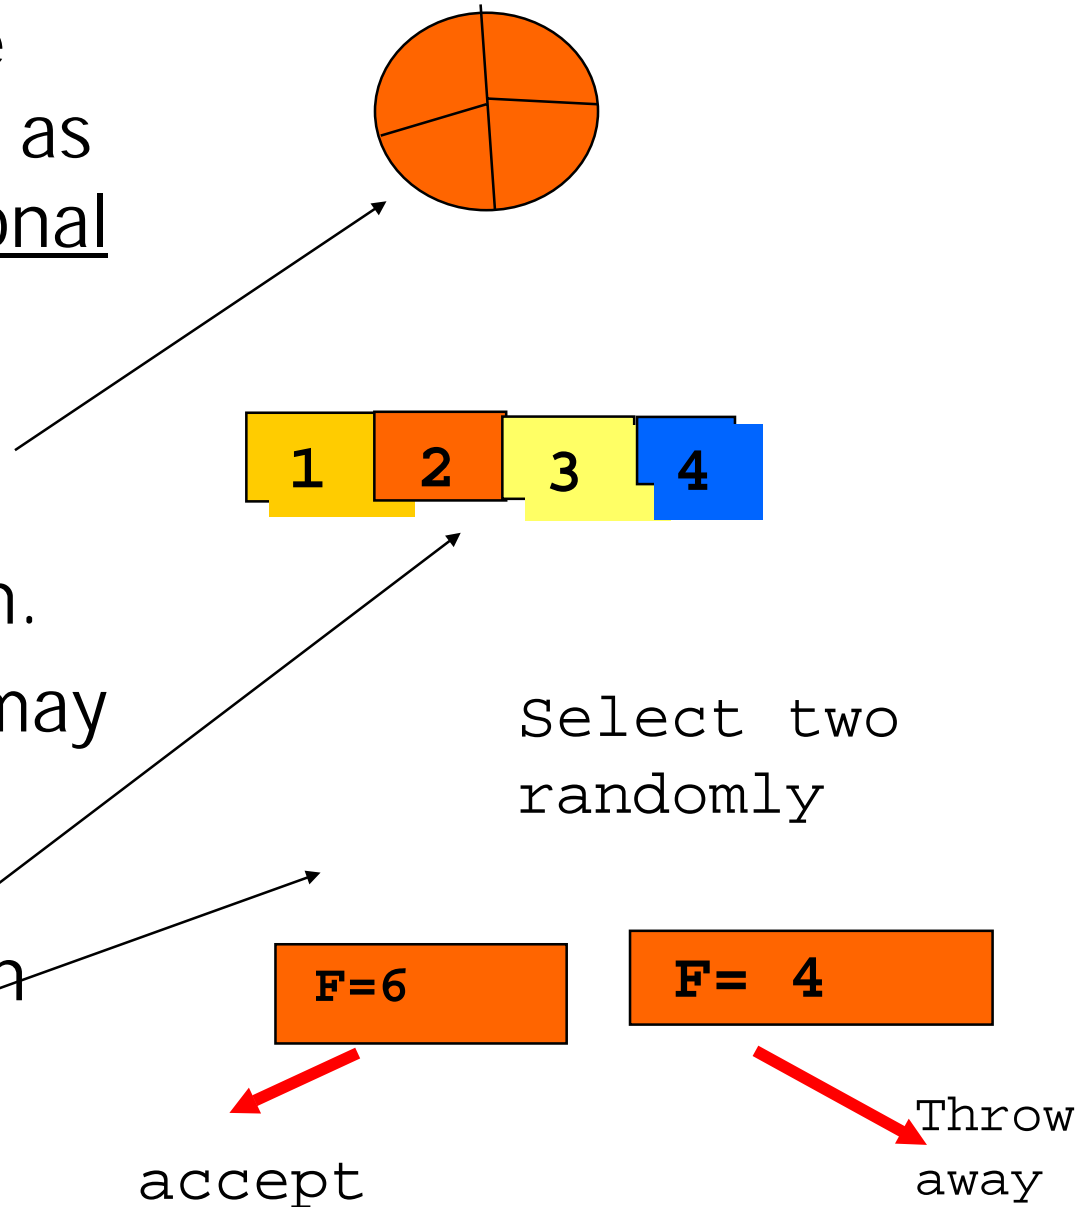

# Parent/Survivor Selection

- Too strong fitness selection bias can lead to sub-optimal solution
- Too little fitness bias selection results in unfocused and meandering search

Give examples  
from biology and  
society

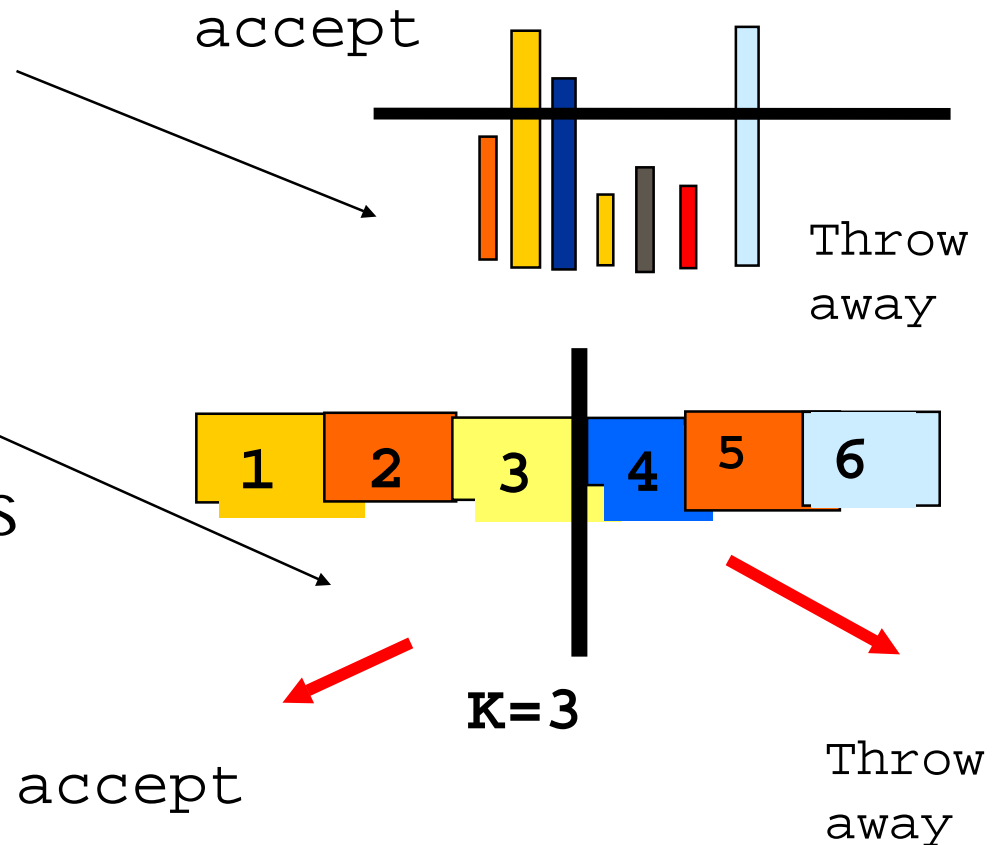

# Parent selection

- In Roulette Wheel the chance to be selected as a parent are proportional to fitness
- If values change by little, the mechanism becomes near random.
- Thus other methods may be used, based on **ranking proportional** (linear selection) or on **tournament**

# Parent selection

- **Threshold method** - select those who have fitness above some value  $T$
- **Elitist method** - kill all but  $k$  best fit individuals

# Tournament Selection Methods

- Binary tournament
  - Two individuals are randomly chosen; the fitter of the two is selected as a parent
- Probabilistic binary tournament
  - Two individuals are randomly chosen; with a chance  $p$ ,  $0.5 < p < 1$ , the fitter of the two is selected as a parent
- Larger tournaments
  - $n$  individuals are randomly chosen; the fittest one is selected as a parent
- By changing  $n$  and/or  $p$ , the GA can be adjusted dynamically

# Mixed Parent/Survivor Selection Strategies

- Strategies
  - Parent selection
    - | Uniform randomly selection
    - | Probability selection : proportional to their fitness
    - | Tournament selection (Multiple Objectives)
      - Build a small comparison set
      - Randomly select a pair with the higher rank one beats the lower one
      - Non-dominated one beat the dominated one
      - Niche count**: the number of points in the population within certain distance, higher the niche count, lower the rank.
    - | Etc.

# Evolutionary Computing

# Fitness Function

- A key component in GA
- Time/quality trade off
- Multi-criterion fitness

## Purpose

- Parent selection
- Measure for convergence
- **For Steady state:** Selection of individuals to die
- Should reflect the value of the chromosome in some “real” way
- Next to coding the **most critical** part of a GA

# Problems with fitness range

- Problem #1. Premature convergence
  - $\Delta\text{Fitness}$  too large
  - Relatively superfit individuals dominate population
  - Population converges to a local maximum
  - Too much exploitation; too few exploration
- Problem # 2. Slow finishing
  - $\Delta\text{Fitness}$  too small
  - No selection pressure
  - After many generations, average fitness has converged, but no global maximum is found; not sufficient difference between best and average fitness
  - Too few exploitation; too much exploration

Thus we want  $\Delta\text{Fitness}$  to be not too small, not too large

# What are the solutions to solve these problems with fitness range?

- Use tournament selection
  - Implicit fitness remapping
- Adjust fitness function for roulette wheel
  - Explicit fitness remapping
    - | Method 1: Fitness **scaling**
    - | Method 2: Fitness **windowing**
    - | Method 3: Fitness **ranking**

Will be explained below

# Method 1: Fitness scaling

- Fitness values are scaled by subtraction and division
  - so that worst value is close to 0 and the best value is close to a certain value, typically 2
    - | Chance for the most fit individual is 2 times the average
    - | Chance for the least fit individual is close to 0
- There are problems when the original maximum is very extreme (**super-fit**)
  - or when the original minimum is very extreme (**super-unfit**)
    - | Can be solved by defining a minimum and/or a maximum value for the fitness

# Example of Fitness Scaling

... this is a kind of normalization of shape that allows to make decisions based on statistics of other but similar examples....

# Method 2: Fitness windowing

Other popular method to deal with fitness function range

- The method is the same as window scaling, except the amount subtracted is the minimum *observed in the  $n$  previous* generations.
- For instance, take  $n = 10$
- There exist the same problems as with scaling

# Method 3: Fitness ranking

- Individuals are **numbered in order** of increasing fitness
- The rank in this order is the **adjusted fitness**
- Starting number and increment can be chosen in several ways, and they influence the results
- No problems with super-fit or super-unfit
- This method is often **superior** to scaling and windowing

# Observe the fitness in generations: Example run

Maxima and Averages of steady state (**St**) and generational (**Ge**) replacement

# Fitness Landscapes

Landscapes are related to selection and fitness functions

- Selection **moves organisms** over a landscape to find peaks
- **Peak** indicates high level of fitness
- Some numbers about the space of such a landscape:
  - image number of genes = 7
  - then  $2^7 = 128$  different *genotypes*
  - **E. Coli** has about 3,000 genes, thus  $10^{900}$  possible genotypes

# Selection - Fitness Landscapes

Smooth landscape

Rugged landscape

Discuss analogy to travellers who want to find highest peak in Himalaya Mountains

# Selection - Fitness Landscapes

Complex organisms -> complex fitness landscape

Problem!

- Random fitness landscape
- Adaptive walk
- Correlated landscapes
- theoretical model -> very nice!

# Multi-Criterion Fitness

. . . Sometimes there is no single best solution criterion. . .

- Pareto Optimal Set
  - If there exists no solution in the search space which dominates any member in the set  $P$ , then the solutions belonging to the set  $P$  constitute a global Pareto-optimal set.
  - Pareto optimal front
- Dominance Check

# Multi-Criterion Fitness

- Dominance and indifference
  - For an optimization problem with more than one objective function ( $f_i, i=1,2,...,n$ )
  - given any two solution  $X_1$  and  $X_2$ , then
    - |  $X_1$  dominates  $X_2$  ( $X_1 \succ X_2$ ), if **Maximizing  $f$**   
 $f_i(X_1) \geq f_i(X_2)$ , for all  $i = 1, \dots, n$
    - |  $X_1$  is indifferent with  $X_2$  ( $X_1 \sim X_2$ ), if  $X_1$  does not dominate  $X_2$ , and  $X_2$  does not dominate  $X_1$

Minimization and maximization problems can be easily converted to one another

# Multi-Criterion Fitness

- Weighted sum

- $F(\mathbf{x}) = w_1 f_1(x_1) + w_2 f_2(x_2) + \dots + w_n f_n(x_n)$

- *Problems?*

- | *Convex and convex Pareto optimal front*

- Sensitive to the shape of the Pareto-optimal front*

- | *Selection of weights?*

- Need some pre-knowledge*

- Not reliable for problem involving uncertainties*

# Multi-Criterion Fitness

- Optimizing single objective

- *Maximize:*  $f_k(\mathbf{X})$

- Subject to:*

- $$f_j(\mathbf{X}) \leq K_j, \quad j \neq k$$

- $\mathbf{X}$  in  $F$  where  $F$  is the solution space.

# Multi-Criterion Fitness

- Weighted sum

- $F(\mathbf{x}) = w_1 f_1(x_1) + w_2 f_2(x_2) + \dots + w_n f_n(x_n)$

- *Problems?*

- | *Convex and convex Pareto optimal front*

- Sensitive to the shape of the Pareto-optimal front*

- | *Selection of weights?*

- Need some pre-knowledge*

- Not reliable for problem involving uncertainties*

# Multi-Criterion Fitness

- Preference based weighted sum  
(**ISMAUT** ***I**mprecisely **S**pecific **M**ultiple **A**tttribute **U**tility **T**heory*)
  - $F(\mathbf{x}) = w_1 f_1(x_1) + w_2 f_2(x_2) + \dots + w_n f_n(x_n)$
  - Preference
    - | Given two known individuals  $\mathbf{X}$  and  $\mathbf{Y}$ , if we prefer  $\mathbf{X}$  than  $\mathbf{Y}$ , then
$$F(\mathbf{X}) > F(\mathbf{Y}),$$
that is
$$w_1(f_1(x_1) - f_1(y_1)) + \dots + w_n(f_n(x_n) - f_n(y_n)) > 0$$

# Multi-Criterion Fitness

- | All the preferences constitute a linear space

$$W_n = \{w_1, w_2, \dots, w_n\}$$

$$w_1(f_1(x_1) - f_1(y_1)) + \dots + w_n(f_n(x_n) - f_n(y_n)) > 0$$

$$w_1(f_1(z_1) - f_1(p_1)) + \dots + w_n(f_n(z_n) - f_n(p_n)) > 0, \text{ etc}$$

- | For any two new individuals  $Y'$  and  $Y''$ , how to determine which one is more preferable?

# Multi-Criterion Fitness

$$\begin{aligned} \text{Min} : \mu &= \sum_k w_k [f_k(\mathbf{Y}') - f_k(\mathbf{Y}'')] \\ \text{s.t.} : & \quad W_n \end{aligned}$$

$$\begin{aligned} \text{Min} : \mu' &= \sum_k w_k [f_k(\mathbf{Y}'') - f_k(\mathbf{Y}')] \\ \text{s.t.} : & \quad W_n \end{aligned}$$

Where  $W_n$  is defined in  
previous slide

# Multi-Criterion Fitness

Then,

$$\mu > 0 \Rightarrow Y' \succ Y''$$

$$\mu' > 0 \Rightarrow Y'' \succ Y'$$

Otherwise,

$$Y' \sim Y''$$

Construct the dominant relationship among some indifferent ones according to the preferences.

Perceptrons, logic decomposition or Neural Nets can be used to create cost functions for these kinds of problems. Linking EA and other Machine Learning/AI methods

# Other parameters of GA

- **Initialization:**
  - Population size
  - Random initialization
  - Dedicated greedy algorithm (smart) to initialize
- **Reproduction:**
  - **Generational:** as described before (insects)
  - **Generational with elitism:** fixed number of most fit individuals are copied unmodified into new generation
  - **Steady state:** two parents are selected to reproduce and two parents are selected to die; two offspring are immediately inserted in the pool (mammals)

# Other parameters of GA (cont)

- **Stop criterion:**
  - Number of new chromosomes
  - Number of new and unique chromosomes
  - Number of generations
- **Measure:**
  - Best of population
  - Average of population
- **Duplicates**
  - Accept all duplicates
  - Avoid too many duplicates, because that degenerates the population (intelt)
  - No duplicates at all

# Other issues

- Global versus Optimal
- Parameter Tuning: hand versus automatic
- Parallelism: software, versus hardware, versus evolvable hardware
- Random number generators; quality of software and hardware realizations

**EIA**

**Applications**

# EA Applications

- Numerical, **Combinatorial** Optimization
- System Modeling and Identification
- Planning and Control
- Engineering Design  
(logic and architectural synthesis)
- **Data Mining**
- **Machine Learning**
- **Artificial Life (Brain Building)**

## Evaluation of EA algorithms

- Acceptable performance at acceptable costs on a **wide range of problems**
- **Intrinsic parallelism** (robustness, fault tolerance)
- Superior to other techniques on **complex problems** with
  - lots of data, many free parameters
  - complex relationships between parameters
  - many (local) optima

## Advantages of EA algorithms

- No presumptions with respect to problem space
- Widely applicable
- Low development & application costs
- Easy to incorporate other methods
- Solutions are interpretable (unlike NN)
- Can be run interactively, accomodate user proposed solutions
- Provide many alternative solutions

## Disadvantages of EA algorithms

- No guarantee for optimal solution within finite time
- Weak theoretical basis
- May need parameter tuning
- Often computationally expensive, i.e. slow

# *Outline of various techniques*

- Plain Genetic Algorithms
- Evolutionary Programming
- Evolution Strategies
- Genetic Programming

# *Evolutionary Programming*

- Individuals are finite-state automata
- Used to solve prediction tasks
- State-transition table modified by uniform random mutation
- No recombination
- Fitness depends on the number of correct predictions
- **Truncation** selection

# Evolutionary Programming: Individuals

Finite-state automaton:  $(Q, q_0, A, \Sigma, \delta, \omega)$

- set of states  $Q$ ;
- initial state  $q_0$ ;
- set of accepting states  $A$ ;
- alphabet of symbols  $\Sigma$ ;
- transition function  $\delta: Q \times \Sigma \rightarrow Q$ ;
- output mapping function  $\omega: Q \times \Sigma \rightarrow \Sigma$ ;

state input	state		
	$q_0$	$q_1$	$q_2$
$a$	$q_0$ $a$	$q_2$ $b$	$q_1$ $b$
$b$	$q_1$ $c$	$q_1$ $a$	$q_0$ $c$
$c$	$q_2$ $b$	$q_0$ $c$	$q_2$ $a$

# Evolutionary Programming: Fitness

***Fitness depends on the number of correct predictions***

# Evolutionary Programming: Selection

Variant of stochastic  $q$ -tournament selection:

Order individuals by decreasing score  
**Select first half** (Truncation selection)

# Evolution Strategies

- Individuals are  $n$ -dimensional vectors of real numbers
- Fitness is the objective function
- Mutation distribution can be part of the genotype  
(standard deviations and covariances evolve with solutions)
- Multi-parent recombination (*more than two parents*)
- Deterministic selection (truncation selection)

# GVA Examples

# Example 1: coding for TSP

## Travelling Salesman Problem

- Binary coding
  - Cities are binary coded; chromosome is string of bits
    - | Most chromosomes code for illegal tour
    - | Several chromosomes code for the same tour
- Path coding
  - Cities are numbered; chromosome is string of integers
    - | Most chromosomes code for illegal tour
    - | Several chromosomes code for the same tour
- Ordinal
  - Cities are numbered, but code is complex ([permutative coding](#))
  - All possible chromosomes are legal and only one chromosome for each tour
- Several others

# Example 2: Function Optimization

- **Problem:** Find the maximum value of a two-variable function

$$F(x_1, x_2) = 21.5 + x_1 \sin(4\pi x_1) + x_2 \sin(20\pi x_2)$$

$x_1$  is in the range  $[-3.0, 12.1]$  and  
 $x_2$  is in the range  $[4.1, 5.8]$

There are several ways to solve this problem: **Classical/Search/GA . . .**

# Example 2: (cont)

## Representation of a real number

- The **first problem** is one of representation
  - how do you create a binary representation of a real number?
- **SOLUTION:** determine a level of precision and divide the range into **equal sized intervals**
  - if **p** is the level of precision and the interval is **L** *then* the number of bits required is the number of bits in the binary representation of  $L \times 10^p$ 
    - | for  $x_1$  the interval is -3 to 12.1 so  $L = 15.1$ 
      - 1 decimal place of precision requires 8 bits ( $15.1 \times 10^1$ )
      - 2 decimal places of precision require 11 bits ( $15.1 \times 10^2$ )

# Example 2: (cont)

## Conversion

- To convert a binary number **b** to a real number **x** use:

$$x = d + i \left( \frac{L}{R} \right)$$

Where

**i** is the integer value of **b**

**d** is the lower value of the range

**L** is the length of the range

**R** is the range of binary integers

For example,  $x_1$  with 4 digits of precision (18 bits), is found to be (in binary): 010101110000110010

**i is 89136**

**L is 15.1**

**R is  $2^{18}-1$**

**d is -3**

$$x = -3.0 + 89136 \left( \frac{15.1}{2^{18} - 1} \right) = 2.1344$$

## Example 2: (cont)

# Complete Representation

- $x_2$  has a range of 1.7, so for 4 decimal places of precision it requires 15 bits
- Hence, a single chromosome for both variables requires  $18 + 15 = 33$  bits
  - the first 18 bits represent  $x_1$
  - the last 15 bits represent  $x_2$

For example, this chromosome represents two real numbers

<010001001011010000|111110010100010>

$x_1 = 1.0524$        $x_2 = 5.7553$

## Example 2: (cont)

### Start a GA

- Determine a population size,  $n$
- Using a random number generator, construct  $n$  binary strings
- Determine the fitness of each random solution

# Example 2: (cont)

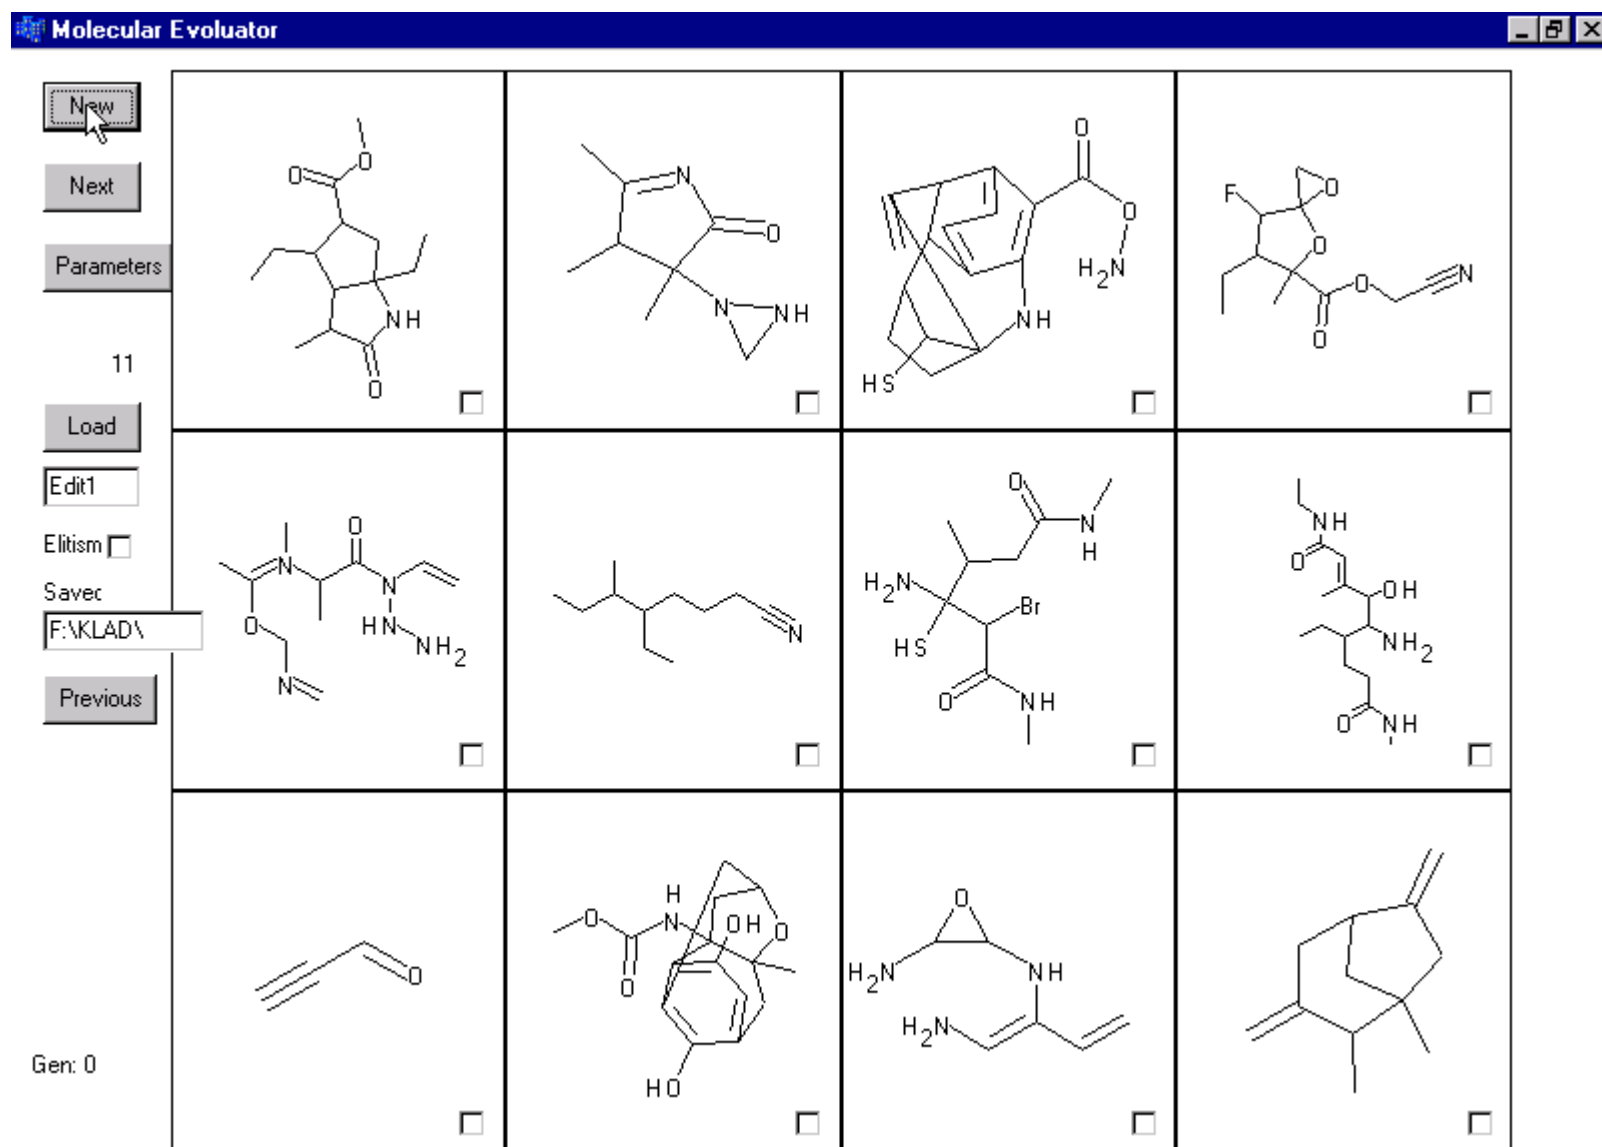

## Example Run

**Population size is 20,  
fitness is the function  
value**

Point	Binary Representation	Value

Constraints, rules and partial cost functions

User part of the loop, subjective cost functions,  
GA-based Computer Aided Design, Computer-Aided  
Art, etc.

# Example GP Problem

- Santa-Fe Trail Problem

**Fitness:** How much food collected

Individual program  
on the previous  
slide generated on  
7th generation  
solved the problem  
completely

# Example GP Problem (cont)

**Examples:** Artificial Ant Problem. Given a set environment with a trail of food, goal is to get as most of the food as possible in a given timeframe

Functions: IF-FOOD, PROGN

Terminals: ADVANCE, TURN LEFT, TURN RIGHT

After 51 generations with population of 1000, following individual emerged that got all the food:

```
(If-Food (Advance)
  (Progn (turn-right)
    (If-Food (Advance) (Turn-Left))
    (Progn (Turn-left)
      (If-Food (Advance) (Turn-Right))
      (Advance))))
```

# Variant of Ants - Emergent Collective Behavior

**Fitness:** Food collected by all ants and returned to nest in given time period

Programs evolved to demonstrate **collective intelligent behavior**, lay pheromone trails
