(Received 16 February 1988)

The entire class of integrals containing a product of $N$ 1s hydrogenic orbitals and $M$ Coulomb or Yukawa potentials (with arguments that are linear combinations of the $m = N + M$ coordinates of integration) with $m$ plane waves is analytically reduced from a $3m$-dimensional integral to a $(M + N - 1)$-dimensional integral.

I. INTRODUCTION

In the preceding paper the Fourier transform of the multicenter product of 1s hydrogenic orbitals and Coulomb or Yukawa potentials was found. Then the dimensionality of the subsequent integration over plane waves with this product of orbitals and potentials was reduced from $3(m + 1)$ to $N + M - 1$, where $m = N + M$. The product of orbitals and potentials treated in that paper was not the most general class since they had the Fourier transform coordinate in common. The present paper extends this analytical reduction to the general class of integrals composed of products of plane waves with 1s hydrogenic orbitals and Coulomb or Yukawa potentials in which the arguments are arbitrary linear combinations of the coordinates of integration.

The product of orbitals and potentials is first Fourier transformed using

$$S_{1s,\ldots,1s}^{\lambda_1,\ldots,\lambda_N;\eta_1,\ldots,\eta_M}(p_1,p_2,\ldots,p_m) = \int d^3x_1 \cdots d^3x_m e^{-i(p_1 \cdot x_1 + \cdots + p_m \cdot x_m)}$$

$$\times u_{1s}^{\lambda_i}(R_i) \cdots u_{1s}^{\lambda_N}(R_N) V_{\eta_1}(R_{N+1}) \cdots V_{\eta_M}(R_{N+M}) ,$$

where

$$R_i = \sum_{j=1}^{m} t_{ij} x_j .$$

The procedure is similar to the previous work, as would be the extensions to excited states noted therein. First one introduces the Feynman representation for the denominators in the Fourier transforms of the orbitals and potentials to allow addition of all momenta from these denominators within a single denominator. Using an additional integral transformation, this denominator is elevated into an exponential, allowing the momenta in the plane waves to be added in so that all angular dependence lies within a single quadratic form. Then orthogonal transformations are invoked to diagonalize this quadratic form first with respect to momenta and then with respect to the spatial coordinates. But after integration over momentum and spatial coordinates, the elements of the diagonalized matrices appear only in the form of the determinant of the matrices, which are invariant under the orthogonal transformations, so that these transformations do not need to actually be found. One needs only to calculate the discriminants of the original quadratic forms.

II. TRANSFORMATIONS AND INTEGRATIONS

The product of orbitals and potentials is first Fourier transformed using (in atomic units)

$$u_{1s}^{\lambda}(R) = \left( \frac{\lambda}{\pi} \right)^{5/2} \int d^3k \frac{e^{ik \cdot R}}{(\lambda^2 + k^2)^{3/2}} ,$$

where

$$\lambda = \frac{Z}{a_0} ,$$

and

$$V_{\eta}(R) = \frac{e^{-\eta R}}{R^2} = \frac{1}{2\pi^2} \int d^3k \frac{e^{ik \cdot R}}{\eta^2 + k^2} , \quad \eta \geq 0 .$$
Then
\[ S = \left[ \frac{\lambda_1}{\pi} \frac{\lambda_2}{\pi} \cdots \frac{\lambda_N}{\pi} \right]^{5/2} \frac{1}{(2\pi^2)^M} \int d^3x_1 \cdots d^3x_m \int d^3k_1 \cdots d^3k_N d^3k_{N+1} \cdots d^3k_{N+M} \]
\[ \times \left( -i(p; x_1 + \cdots + p_m x_m - k_1 R - \cdots - k_N R_N - k_{N+1} R_{N+1} - \cdots - k_{N+M} R_{N+M}) \right) \times \left( (\lambda_1^2 + k_1^2)^2 \cdots (\lambda_N^2 + k_N^2)^2 (\eta_1^2 + k_{N+1}^2)^2 \cdots (\eta_{N+M}^2 + k_{N+M}^2)^2 \right) . \]

Note that at this stage one could integrate over the x's to obtain δ functions in m of the N + M momentum variables. But sequential integration using these δ functions becomes increasingly difficult as N and M increase and does not decrease the final number of integrals except in special cases noted in the previous paper, such as when m = N + M.

The next step is to introduce the standard integral transform for the denominators, generalized to allow arbitrary powers of the denominators,
\[ \frac{1}{D_1^{m_1} D_2^{m_2} \cdots D_n^{m_n}} = \frac{n + \sum m_i - 1}{(m_1)! (m_2)! \cdots (m_n)!} \int_0^1 d\alpha_1 \int_0^1 d\alpha_2 \cdots \int_0^1 d\alpha_N \alpha_1^{m_1} \alpha_2^{m_2} \cdots \alpha_N^{m_N} \delta \left[ 1 - \sum_{i=1}^n \alpha_i \right] \]
\[ \left( \sum_{i=1}^n \alpha_i D_i \right)^{\sum m_i - 1} . \]

and, to allow addition of momentum vectors from the plane waves and the denominators, the additional transformation
\[ (v-1)!D^v = \int_0^\infty d\rho \rho^{v-1} e^{-\rho D} . \]

Then (1) can be written in terms of a single quadratic form
\[ S = \left[ \frac{\lambda_1}{\pi} \frac{\lambda_2}{\pi} \cdots \frac{\lambda_N}{\pi} \right]^{5/2} \frac{1}{(2\pi^2)^M} \int_0^1 d\alpha_1 \int_0^1 d\alpha_2 \cdots \int_0^1 d\alpha_N d\alpha_{N+M} \cdots \alpha_N^\delta \left[ 1 - \sum_{i=1}^n \alpha_i \right] \]
\[ \times \int_0^\infty d\rho \rho^{N+M-1} \int d^3x_1 \cdots d^3x_m \int d^3k_1 \cdots d^3k_{N+M} e^{-\rho Q} , \]

where
\[ Q = V^T W V , \]
\[ V^T = \begin{pmatrix} k_1 & k_2 & \cdots & k_{N+M} & 1 \end{pmatrix} , \]
\[ W = \begin{pmatrix} \alpha_1 & 0 & \cdots & 0 & b_1 \\ 0 & \alpha_2 & \cdots & 0 & b_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & \alpha_{N+M} & b_{N+M} \\ b_1 & b_2 & \cdots & b_{N+M} & C \end{pmatrix} , \]
\[ C = q + \frac{i}{\rho} \sum_{i=1}^m x_i p_i , \]
\[ q = \sum_{i=1}^N \lambda_i^2 \alpha_i + \sum_{i=N+1}^{N+M} \eta_i^2 \alpha_i , \]

and
\[ b_j = - \frac{i}{2\rho} \sum_{i=1}^m t_{ji} x_i . \]

By an orthogonal transformation and a simple translation in [k_1, k_2, \ldots, k_N] space (with Jacobian = 1), Q may be reduced to diagonal form
\[ Q' = a_1 k_1^2 + a_2 k_2^2 + \cdots + a_{N+M} k_{N+M}^2 + c' , \]
allowing the k integrals to be done, allowing the k integrals to be done,
ANALYTICALLY REDUCED FORM FOR THE CLASS OF...

\[ \Lambda_{ij} = \prod_{i \neq j}^{N+M} \alpha_i = \delta_{ij} \prod_{i=1}^{N+M} \alpha_i . \]  

Consider the last line of (19). Gathering the x-dependent parts, from (13) and (15),

\[ \Omega = \varphi \Lambda + H , \]  

where

\[ H = -X^T X, \]

\[ \chi^T = \begin{bmatrix} x_1 & x_2 & \cdots & x_m \end{bmatrix}, \]

\[ Z = \begin{bmatrix} z_{11} & z_{12} & \cdots & z_{1m} & \Lambda \alpha_1 \\ z_{21} & z_{22} & \cdots & z_{2m} & \Lambda \alpha_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ z_{m1} & z_{m2} & \cdots & z_{mm} & \Lambda \alpha_m \end{bmatrix} \]

and

\[ z_{ij} = \sum_{k=1}^{N+M} t_{ik} t_{kj} \prod_{k \neq i}^{N+M} \alpha_k . \]

As with (16), one may use an orthogonal transformation and a translation in \( \{x_1, x_2, \ldots, x_m\} \) space to reduce \( H \) to diagonal form,

\[ H' = \begin{bmatrix} z'_1 & & & \\ & z'_2 & \cdots & \\ & & \ddots & \\ & & & z'_m \end{bmatrix} + g', \]

where \( g' \), the quadratic form in the external momenta \( p_j \), and \( z'_i \) are non-negative. Defining the invariant determinant

\[ z'_1 z'_2 \cdots z'_m = \Delta \equiv \begin{vmatrix} z_{11} & z_{12} & \cdots & z_{1m} \\ z_{21} & z_{22} & \cdots & z_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ z_{m1} & z_{m2} & \cdots & z_{mm} \end{vmatrix} \]

allows the final term of (26) to be written

\[ g' = -\frac{\zeta}{\Delta} , \]

where \( \zeta \) is the invariant determinant

\[ \zeta = \left| Z \right| = \Lambda^2 \sum_{i=1}^{m} \sum_{j=1}^{m} p_i \cdot p_j (-1)^{i+j+1} \Delta_{ij} . \]

Then, from (19) and (21),

\[ c' = (\varphi \Lambda + H) / \Lambda , \]

so that, from (26) and (28),

\[ \rho c' = \rho \left[ \varphi - \frac{\zeta}{\Delta} \right] + \frac{z'_1}{4\rho \Lambda} x'_1^2 + \frac{z'_2}{4\rho \Lambda} x'_2^2 + \cdots + \frac{z'_m}{4\rho \Lambda} x'_m^2 . \]

Then the final result is

\[ \int d^3 x'_1 \cdots d^3 x'_m \exp \left[ - \left( \frac{z'_1}{4\rho \Lambda} x'_1^2 + \frac{z'_2}{4\rho \Lambda} x'_2^2 + \cdots + \frac{z'_m}{4\rho \Lambda} x'_m^2 \right) \right] \]

and the \( \rho \) integral is, from (8),

\[ \int_0^\infty d\rho \rho^{2N+M-1-3(N+M)/2+3m/2} e^{-\rho (\varphi - \zeta / (\Delta \Lambda))} \]

Then the final result is

\[ S_{11, \ldots, N; \eta_1, \ldots, \eta_M}(p_1, p_2, \ldots, p_m) = \frac{(\lambda_1 \cdots \lambda_N)^{3/2} 2^{3m-M-M} \Gamma((3m+N-M)/2)}{\pi^{N+M/2-3m/2}} \]

\[ \times \int_0^1 d\alpha_1 \cdots \int_0^1 d\alpha_{N+M} \alpha_1 \cdots \alpha_N \delta \left[ 1 - \sum_{i=1}^{N+M} \alpha_i \right] \Lambda^{3m+(N-M-3)/2} \Delta^{(3m+N-M-3)/2} e^{-\rho (\varphi \Delta - \zeta)} (3m+N-M)/2 \]

\[ \times \int_0^1 d\alpha_1 \cdots \int_0^1 d\alpha_{N+M} \alpha_1 \cdots \alpha_N \delta \left[ 1 - \sum_{i=1}^{N+M} \alpha_i \right] \Lambda^{3m+(N-M-3)/2} \Delta^{(3m+N-M-3)/2} e^{-\rho (\varphi \Delta - \zeta)} (3m+N-M)/2 \]

Since this expression involves only the invariant determinants, \( \Lambda, \Delta, \) and \( \zeta \), rather than the individual coefficients in the diagonalized quadratic forms (16) and (26), the orthogonal transformations leading to these diagonal forms do not need to be explicitly calculated.

III. CONCLUSION

The present approach has analytically reduced the dimensionality of the entire class of integrals containing the multi-center product of plane waves with ls hydrogenic and Coulomb or Yukawa potentials. The difficult calculus coupled to algebraic manipulation that is necessary for reducing the dimensionality of integrals in a given problem has been done
once and for all so that time may instead be spent on the development and physical meaning of theories. The reader is directed to Ref. 1 for extensions necessary to include excited states and for the case in which all $R_i$ have some $x_j$ in common, allowing a $3(m + 1)$-dimensional integral to be reduced to $N + M - 1$ dimensions.\footnote{\textsuperscript{8}}
