1 **ABSTRACT**

2 Transit goals have typically focused on commuter trips but facilitating urban last-mile freight  
3 logistics is a potential strategy to increase transit ridership and mitigate the demands of parcel  
4 distribution on the transportation network. Presently, most parcel lockers operate out of private  
5 businesses, but consumer surveys have found that transit users may be interested in locker  
6 facilities at transit facilities. The implementation of an unmanned, secure, common carrier parcel  
7 locker system could have benefits for non-transit users as well. This research presents a multiple-  
8 criteria approach for analyzing the potential of public transportation facilities as a host for a  
9 common carrier locker system. Several accessibility and equity metrics, including ridership,  
10 mode of transportation, spatial distribution, and sociodemographic profiles of coverage areas are  
11 utilized. A case study utilizing real-world data from the Portland, OR region and its transit  
12 facilities is used to illustrate accessibility and equity tradeoffs. The results demonstrate that  
13 multiple facility types have potential to host a locker system but there are complex accessibility  
14 and equity tradeoffs to be considered by stakeholders and policy makers when prioritizing  
15 locations.

18 accessibility, equity

1 **INTRODUCTION**

2 E-commerce activity continues to grow worldwide, and business-to-consumer (B2C)  
3 sales in the US are predicted to reach over \$550B by 2024, up from \$360 billion in 2019 (1).  
4 Consumer demand has generated growing parcel volumes and demanded the perception of low  
5 shipping costs, and many retailers mask the true cost of shipping to promote sales. Retailers rely  
6 on competitive logistic strategies to offer increasingly short delivery lead times, high traceability,  
7 and reliability. Although logistical operations have become streamlined in early supply chain  
8 phases, the final segment of delivery–“the last mile”– remains the most expensive and least  
9 efficient segment (2,3). The operational costs of the last mile swell due to order fragmentation,  
10 which precludes economies of scale; many delivery tour stops deliver only one parcel per stop  
11 (4). Looking even further than the last mile, research on “the last 800 feet” finds the  
12 fragmentation of delivery tours to be rife with distinct challenges, such as locating parking (7,8)  
13 and the operations performed outside the freight vehicle (5).

14 As last mile challenges are not easily overcome, some recent innovations look to  
15 alternatives to home delivery destinations. European markets introduced parcel lockers as early  
16 as 2002, but parcel lockers were not implemented in the US until the introduction of Amazon  
17 Hub Locker service in 2011. Subsequently, United States Postal Service (USPS) launched a  
18 gopost® locker pilot in select cities, and UPS developed their Access Point Locker™ network.  
19 FedEx has a limited network of Ship&Get® lockers in Texas, but primarily promotes in-store  
20 shipping centers and on-street drop boxes. USPS and Amazon lockers can receive and hold  
21 freight from UPS and FedEx, which offers some flexibility to their users, but UPS and FedEx  
22 lockers only accept in-network parcels. Under these restrictions, consumers are expected to  
23 travel to multiple collection points to receive parcels from non-cooperating carriers.

24 To offer a locker solution that can compete with the convenience of home deliveries, the  
25 alternative of a common carrier parcel locker system has been conceived to maximize the  
26 consolidation benefits to consumers (6). Since US consumers are likely to have incoming parcels  
27 from multiple couriers, the purpose of a common carrier system reduces consumer pickup travel  
28 by offering a one-stop location for packages from different couriers. Ideally, a common carrier  
29 locker program is independent from any singular courier, due to the proprietary nature of  
30 logistics data and courier operations. Moreover, an automatic/unmanned parcel locker system  
31 can offer consumers more security and privacy than porch drop-offs, and expanded hours of  
32 locker access compared to the lockers that are located within private businesses (7).

33 This paper presents a multiple-criteria approach for reviewing the potential of public  
34 transportation facilities as a host for a common carrier locker system. Special attention is given  
35 to (a) accessibility and (b) equity in comparing possible locker sites. In the accessibility analysis,  
36 special consideration is given to ridership and geometric design criteria. In the equity analysis,  
37 special consideration is given to the spatial coverage areas of the potential locker sites and their  
38 socioeconomic attributes related to income, race, education level, and internet access. The  
39 service area of TriMet, the transit agency for the Portland, OR metropolitan region is used as a  
40 case study for discussing the results of this approach.

41 In this research, the term “transit facility” is used as an umbrella term to describe a  
42 location that includes any one or combination of the following: bus stations, light rail (MAX)  
43 stations, transit centers (TCs), park-and-ride facilities (PaR), and the segments of the downtown  
44 transit mall (Figure 1). More connections and higher ridership are seen in facility types  
45 illustrated towards the right and/or bottom of Figure 1. This analysis focuses on the three types  
46 of facilities demonstrating the highest ridership in the Portland metropolitan region: (a) the

1 *downtown* transit mall with light rail and bus service, (b) *urban* and *suburban* transit centers with  
 2 light rail and bus service, and (c) *suburban* park-and-ride facilities with large *auto parking*  
 3 capacity in addition to light rail and/or bus services.

4 **Figure 1 Defining "transit facility" to include different kinds of transit locations**

5  
6  
7  
8 **LITERATURE REVIEW**

9 There is a wide range of issues related to freight lockers. To facilitate the review of key  
 10 findings, the literature review has been organized into five subsections. Paper contributions are  
 11 summarized at the of this section.

12  
13 **Advantages of freight lockers over conventional collection points**

14 In spite of the popularity of home delivery, many residences do not have a secure means for  
 15 package reception; requiring a signature for package delivery is a traditional means documenting  
 16 successful package reception. Not only are these signatures inefficient for the courier, but they  
 17 may also inconvenience the consumer and may cause the delivery to “fail” if the resident is away  
 18 or cannot hear or respond to the doorbell. The development of a publicly accessible, self-serve,  
 19 24/7 parcel locker system does not require a signature for security; rather, the use of the  
 20 temporary access code on the electronic locker can provide proof of pickup.

21 In the US, collection point pickups often serve as an undesirable routing solution after  
 22 home delivery fails, typically utilized only after time and labor are wasted on unsuccessful home  
 23 deliveries, and the last-mile connection is shifted to a consumer pickup trip (6–8). If the  
 24 collection point operates inside a private business (such as convenience or box stores), staff labor  
 25 may be required to provide the necessary customer service for the package pickup. This  
 26 arrangement limits pick-up availability to the operating hours of the hosting business (9–11).  
 27 Freight lockers can uncouple package pickup from the constraints of in-store collection points.

28  
29 **Market viability**

30 Though parcel locker service can reduce emissions and repeat-failed deliveries, most e-  
 31 commerce consumers prefer home delivery. Belgian surveys find that 75% of respondents prefer  
 32 home delivery (12) and Chinese surveys find that only 22% of consumers prefer collection points  
 33 and parcel lockers (13). Even in countries with established locker programs, actual usage rates of  
 34 collection points or parcel lockers range from about 10% to 20% (14,15). Low adoption rates  
 35 may be partly due to a lack of familiarity of parcel lockers as a delivery option (16), or because

1 the option is not yet offered by many online stores (17). The initial audit of the USPS gopost  
2 pilot identified that its foremost need for success was increased locker utilization (18).  
3 Ultimately, Iwan et al. found the biggest barrier in the adoption of locker use is that consumers  
4 are required to make the final leg of the journey themselves (9).

5 Despite low adoption rates, consumer interest in parcel lockers or collection points may  
6 be growing. Consumers are highly motivated by free delivery options; 52% of US online  
7 shoppers would consider delivery alternatives if it meant avoiding delivery charges (19).  
8 Additionally, as consumers become more reliant on e-commerce for sensitive or costly goods,  
9 the value of secure delivery increases. In 2016, a US home security company nationwide study  
10 found that 45% of the 2,000 survey respondents have had a parcel stolen or known someone who  
11 has (10). These negative experiences may also increase interest in freight lockers.

12 Multimodal travelers may be distinctly amenable to locker use. Among light rail  
13 passengers who shop online, 14% of survey respondents claimed a parcel locker or collection  
14 point was one of their top preferred locations to pick up parcels, and 40% to 67% respondents  
15 stated a willingness to use a common carrier locker system at a light rail station (6). Similarly,  
16 nearly a quarter of survey respondents in Brussels prefer parcel pick-up at transit-oriented  
17 locations (25).

18 Among Polish consumers already using collection points, the majority (up to 79%) of  
19 users prefer lockers located close to home or to their employment (9,17). Almost 15% of the  
20 users surveyed indicated they would use the parcel lockers more often if they were “better  
21 located”, particularly in proximity to public transport, shops, or supermarkets. New Zealand  
22 consumers echoed a desire for lockers at supermarkets, likely because they are a frequent  
23 destination, and amenable to trip-chaining (20).

#### 24 **Locker accessibility: mode choice and convenience of access**

25 When studying VMT and carbon emission tradeoffs between home delivery and consumer travel  
26 it is key to consider modes and vehicle engine type and efficiency (21). Utilizing a personal  
27 automobile to access a locker will increase VMT, but locker pickup trips made via active travel  
28 (walking, biking, transit) are more energy efficient and produce lower demands on the street  
29 network.  
30

31 Kedia et al. asked consumers about their willingness to use active transport modes to  
32 access collection points (20). Over half of the respondents (54%) were willing to walk or cycle to  
33 the collection point. The mean maximum tolerable distances to walk and cycle were 1.7 km (1  
34 mi) and 2.33 km (1.4 mi), respectively. Light rail riders surveyed by the University of  
35 Washington Urban Freight Lab gave a three to six block range as the most common answer to  
36 the question of how far they were willing to walk with a parcel (6). Researchers also noted that a  
37 relatively high proportion (24% to 42%) of riders said they were willing to walk seven or more  
38 blocks with a parcel. Survey results of parcel locker users in Brussels found that 12% to 15% of  
39 users accessed the parcel lockers via public transport, as many as one-third of users traveled on  
40 foot, and 18% to 23% of users traveled by bicycle (14). Moroz and Polkowski found that 44% of  
41 Polish millennials using parcel machines collect their parcels on foot (8).

42 Based on survey responses in the cited literature, the accessibility to a parcel locker is  
43 likely to influence the utilization of such a delivery service. For urban areas in the Eastern part of  
44 the Paris region, the population is, on average, only 1.6 km (1 mi) in Euclidean distance from the  
45 nearest pickup point. Additionally, half of the pickup points in this region are located within 300  
46 m (less than 1,000 ft) of a commuter railway station (10). InPost prefers to locate their parcel

1 lockers in areas of high population density, high traffic pedestrian areas, and near local  
2 commuting hubs (9). Lee et al. agrees that accessibility to the parcel lockers is an important  
3 factor to consider when selecting an optimal location (22). Placing them along the daily life path  
4 of consumers or near public transportation is believed to enhance their utilization. When  
5 discussing evaluation criteria for light rail-locker sites, residential density and walkability were  
6 paramount to the majority of the stakeholders involved (6). High foot traffic also promotes an  
7 “eyes on the street” effect, giving pedestrians a greater perception of security (23). Perceived and  
8 actual security supports the use of lockers for receiving items of value, as opposed to a  
9 conventional front door drop-off. Additionally, since parcel lockers have not yet saturated the US  
10 market, high visibility may be advantageous to promote utilization of this delivery alternative.

### 11 **Pandemic and resiliency considerations for parcel access**

12 At the time of authorship, Covid-19 has altered many aspects of travel and day-to-day activities,  
13 including transit volume and e-commerce volume. At this point it is uncertain how transit  
14 ridership, the economy, and the workplace will evolve. Evidence is growing that transit is highly  
15 utilized by essential workers and those who cannot work from home (24,25), justifying a  
16 prioritization of systems that serve such workers. Moreover, self-service lockers are compatible  
17 with social distancing measures and an efficient, contactless method of delivery. Technological  
18 changes and the pandemic are also fostering the development of autonomous delivery vehicles  
19 (26,27) that could efficiently complement unmanned lockers.

20 Other disasters—earthquakes, hurricanes, wildfires, landslides—can strain the normal  
21 transportation operations and home deliveries. In an emergency situation, e-commerce deliveries  
22 may be hindered, but resiliency planning also plans for a recovery period, the time in between  
23 crisis and the return to normality. Resiliency planners realize that consolidated distribution  
24 systems may be particularly advantageous to a recovering transportation system. A transit-  
25 oriented locker system offers an additional layer of logistical infrastructure, and any investments  
26 in a transit facility’s pedestrian and bicycle access will be advantageous for the access of the  
27 lockers.  
28

### 29 **Lockers as a more equitable approach to on-demand home delivery**

30 The locker literature has not yet addressed equity considerations. However, previous research in  
31 Portland has already shown that package delivery can provide access to goods and services for  
32 many groups that are mobility impaired or face other accessibility barriers (28). Research about  
33 the adoption of e-commerce by disadvantaged groups finds that they are less likely to adopt  
34 home delivery indicating a strong correlation among low home delivery rates, transit use, low-  
35 income households, low education levels, and non-white populations in the Portland region (29).  
36 Existing home delivery options have apparent barriers to disadvantaged and transit-using  
37 populations. Hence, this research presents an equity analysis, to demonstrate that the selection of  
38 locker sites should be linked with equity goals, particularly in light of racial, educational, e-  
39 commerce adoption, and income disparities.  
40

41  
42 Overall, much of the reviewed literature has relied on consumer surveys to gauge  
43 potential usage or mode of access for parcel lockers. In contrast, this research focuses on  
44 evaluating transit sites as potential common carrier locker sites with a novel emphasis on equity  
45 (there is a growing discussion around transportation equity that is absent in the locker literature).  
46 Both performance metrics and a quantitative assessment of accessibility and equity are provided.

1 A further contribution of the research is to utilize real-world data to highlight the complex  
2 tradeoffs between potential locker utilization, equity metrics, user convenience, and spatial  
3 coverage. The analysis and findings are useful for future policy makers and transportation  
4 practitioners in evaluating common carrier parcel locker locations as an alternative for last-mile  
5 logistic solutions. In this research a freight locker system a transit facilities is discussed with the  
6 assumption that the lockers would be primarily used as the intended delivery destination, and  
7 secondarily utilized as a collection point for failed home deliveries.

## 8 9 **ACCESSIBILITY ANALYSIS**

10 This section describes and presents the results of the accessibility analysis where special  
11 consideration is given to ridership, connectivity, and geometric design.

### 12 13 **Connectivity and ridership criteria**

14 Ridership is an important consideration when evaluating transit sites for their potential in hosting  
15 a common carrier locker system. Locker systems located at transit stops with higher ridership  
16 levels (i.e., more boardings, alightings, transfers, and/or foot traffic) have the potential to serve  
17 more people and therefore locations with higher transit ridership are preferred when considering  
18 site alternatives.

19 TriMet publishes public ridership reports with the number of ons/offers at the stop-level, by  
20 route, and aggregated by transit centers. The data used in this research was from the fall quarter  
21 of 2019 (30), before normal traffic patterns were altered by the Covid-19 pandemic. It is worth  
22 noting that at the time of authorship, the pandemic response is not yet resolved, and ridership  
23 patterns may not return to the same pre-pandemic pattern. Future review should evaluate this  
24 approach after transportation patterns have re-stabilized.

25 For this analysis, ridership totals were tabulated for transit centers and park and ride  
26 facilities (which may serve multiple stops) and for segments of the downtown transit mall to  
27 identify facilities with the greatest activity.

28 The transit mall requires a different type of analysis. The transit mall runs along two  
29 adjacent one-way streets and has rail stops positioned four to five blocks apart with multiple bus  
30 stops located in the blocks between the rail stops. Given the proximity of stops, aggregation of  
31 ridership by segments was performed to more accurately capture the high levels of activity  
32 occurring in the area. To create a contextually relevant aggregation level of passenger boardings  
33 and alightings, the transit mall was partitioned into directional segments so that most segments  
34 included one rail stop at their origin and terminated just prior to the following downstream rail  
35 stop (segments on the ends of the transit mall included a rail stop at both their origin and  
36 terminus). Figure 2 illustrates these transit mall segments.

37

Figure 2 Defining segments of the downtown transit mall

13  
14  
15  
16  
17  
18  
19  
20  
21

Table 1 lists the top 20 transit facilities by ridership volumes, as ranked by total ons and offs in fall 2019. Observations about the connectedness of these locations and facility types are provided, as well as data about the size of the parking facilities at PaR stations. There is a direct relationship between connectivity and ridership. Locations with four rail connections (the maximum possible) tended to have the highest ridership volumes. Lombard is the least connected TC of the high-volume list, with only one rail connection and two bus route connections. The 13<sup>th</sup> highest ridership location is the Lloyd Center MAX (light rail) station, whose ons/offs quantity reflects the aggregation of one rail stop and two connecting bus stops that are no more than a block away. This indicates that the ridership activity of a transit facility may be undervalued if only looking at ridership level data in the transit facility itself. A transit facility that connects several high volume bus routes can have foot traffic on par with or greater than other TCs, such as Hollywood Transit Center with the 15<sup>th</sup> highest ridership. Thus, attention should be paid to the number of connections and coverage of the routes that feed into the transit facility area in addition to ridership numbers. Spatial coverage of the transit facilities is discussed in more detail in the Equity Analysis section.

Ultimately, the numbers of the case study indicate that most of the high-ridership transit facilities are within the central city, where PaR facilities are absent. In fact, over half of the 20 highest ridership locations are segments of the downtown transit mall.

4

**Geometric design criteria**

5  
6  
7  
8  
9  
10  
11

The accessibility of transit facilities for the distribution and retrieval of parcels should also be discussed in terms of their geometric design. A common carrier locker system should enhance the utility of the transit facility and not impede the transit services. Considerations for a loading/unloading zone that could accommodate parcel delivery vehicles without interfering with transit activities should be made. Furthermore, turning radii and sight lines should be conducive to these delivery vehicles.

12  
13  
14  
15  
16  
17

Fortunately, transit centers are designed for heavy vehicles (i.e., buses), so delivery trucks or vans would be able to maneuver through them easily. However, careful design development is needed to orient the locker facility such that the number of bus/truck and truck/pedestrian/bicyclist conflicts is minimized. Compared to transit centers in denser areas, the park-and-rides in the suburbs generally have more flexible space to accommodate freight or parcel delivery vehicles (Figure 3).

18  
19  
20  
21  
22  
23

At transit facilities, there could be dedicated loading/unloading zones for delivery vehicles serving the lockers, placed at locations that minimize conflicts with transit vehicles. If an agreement were made such that locker-loading deliveries occurred outside of peak transit service hours, delivery vehicles could potentially use empty bus bays for speedy loading/and unloading.

1  
2 **Figure 3 Street view of the Clackamas TC covered parking facility (Google Earth)**  
3

4 Along the transit mall, siting lockers at one of the bus stops between light rail stations  
5 is preferable for staging needs, given the curbside placement of rails at rail stations. Bus stops  
6 between rail stations have bays that can accommodate multiple 40-ft. buses. Figure 4 shows the  
7 layout of a bus station between rail stops on the transit mall. The bus bay is clearly visible, and  
8 the sightlines would allow multi-tasking transit riders to pick up their parcel while keeping an  
9 eye on the advancing buses and rail cars while retrieving their parcel. These stations already have  
10 trash cans, electrical wiring, and an established presence in the urban design of downtown.

11 Geometric design is also important for people with mobility impairments and/or and  
12 wheelchair users. There is a correlation between the number of wheelchair lifts, overall ridership,  
13 and comfort and accessible design at transit facilities (31).  
14

15 **Figure 4 Transit mall: bus stop, bus bay, and sightlines of upstream light rail cars (Google Earth)**  
16  
17

1 Finally, the overall design of each facility and its urban context may be also relevant. For  
2 example, the Rose Quarter TC (Figure 5) has high ridership and connectivity but also some  
3 areas with geometric constraints, such as narrow sidewalks, bridges and columns, traffic  
4 infrastructure, and rails. This is an inflexible setting that presents major design challenges for  
5 siting and orienting the locker for accessibility by both consumers and freight vehicles.  
6

7  
8 **Figure 5 Street view of light rail stations at the Rose Quarter TC**  
9

## 10 **EQUITY ANALYSIS**

11 This section describes and presents the results of the equity analysis. Equity metrics  
12 related to population coverage areas by transportation mode, population and employment  
13 distribution, and key socioeconomic characteristics (income, race, education level, and internet  
14 access) of the covered areas are presented and compared among high ridership facilities. Access  
15 to basic goods, services, and activities is a key component in accessibility-based transportation  
16 equity evaluations and mail and package distribution is considered a basic service. An example  
17 of the importance of mail and package delivery is the USPS mandate of providing, in many  
18 places very expensive, universal service obligation or USO (32).

19 To process spatial data and to visualize and quantify equity metrics the open source R  
20 environment, version 4.0.2, and the SF package, version 0.9-8, were utilized.  
21

### 22 **Mode of transportation**

23 The mode of transportation by which travelers access transit facilities is an important equity  
24 consideration. Riders with of lower income households have been linked with lower rates of  
25 vehicle ownership, access to jobs, and other opportunities (33). Thus, transit sites with higher  
26 walking/bicycling accessibility may be particularly beneficial to transportation disadvantaged  
27 populations.

28 To determine the mode-specific accessibility to transit facilities, modal buffers of  
29 Euclidean distances were created around the high-ridership facilities to estimate the population  
30 living within reasonable walking, biking, and driving distances. Population data provided by the  
31 American Community Survey (ACS) 2018 5-year estimates (34) at the US Census block group  
32 level (the smallest level of detail publicly available) was assumed to be uniformly distributed

1 throughout the enumeration unit. The population within the modal buffers was then estimated  
2 using simple areal proportioning.

3 A half-mile walking distance was assumed as the threshold of a comfortable pedestrian  
4 trip to access transit facilities. This threshold is congruent with the default walk limits in the  
5 TriMet Trip Planner tool. For commutes chaining a bicycle trip to a transit trip, a 2005 survey  
6 found that Portland's average bicycle trip to access light rail was 2.1 km (1.3 mi) long (35).  
7 Though the study's sample size was small ( $n = 36$ ), the trip lengths are based on actual commuter  
8 trips, and are similar to findings in other studies. This threshold is more conservative than the  
9 default bicycle limit in the TriMet Trip Planner tool, which is set at 3 miles. Lastly, a driving  
10 threshold was defined for users accessing PaR connections. A 2011 TriMet memo detailing the  
11 expected use as justification for new PaRs assumed a catchment area around PaRs based on a 10-  
12 minute drive. Since driving speeds vary greatly based on street type, an estimated average travel  
13 speed was based on the region's average commute length of 7.1 miles, and taking 26 minutes  
14 (36). From these averages, a peak travel speed of 16.4 mph was derived. Thus, the catchment  
15 assumption of a 10-minute drive translates into a 2.73-mile range.

16 Because multi-modal access was estimated through buffers of Euclidean distances,  
17 correction factors based on the mean circuitry of Portland's driving and walking networks were  
18 applied to the expected driving and walking distances (37). Additionally, although cyclists can  
19 legally travel on any of the streets in Portland except the intracity freeways, Portland cyclists  
20 chose more comfortable routes with lower stress levels than using the shortest route possible  
21 (38). Based on the literature 0.24 miles of extra distance for cyclists was considered. The  
22 Euclidian buffer for bicycle trips was adjusted for this average routing cost in addition to the  
23 network circuitry for the drivable/bikeable street network. The locations of the top 20 TriMet  
24 facilities by ridership and their modal buffers are shown in Figure 6 where the bottom map  
25 provides location of the facilities in the TriMet service region and the top map more detail.

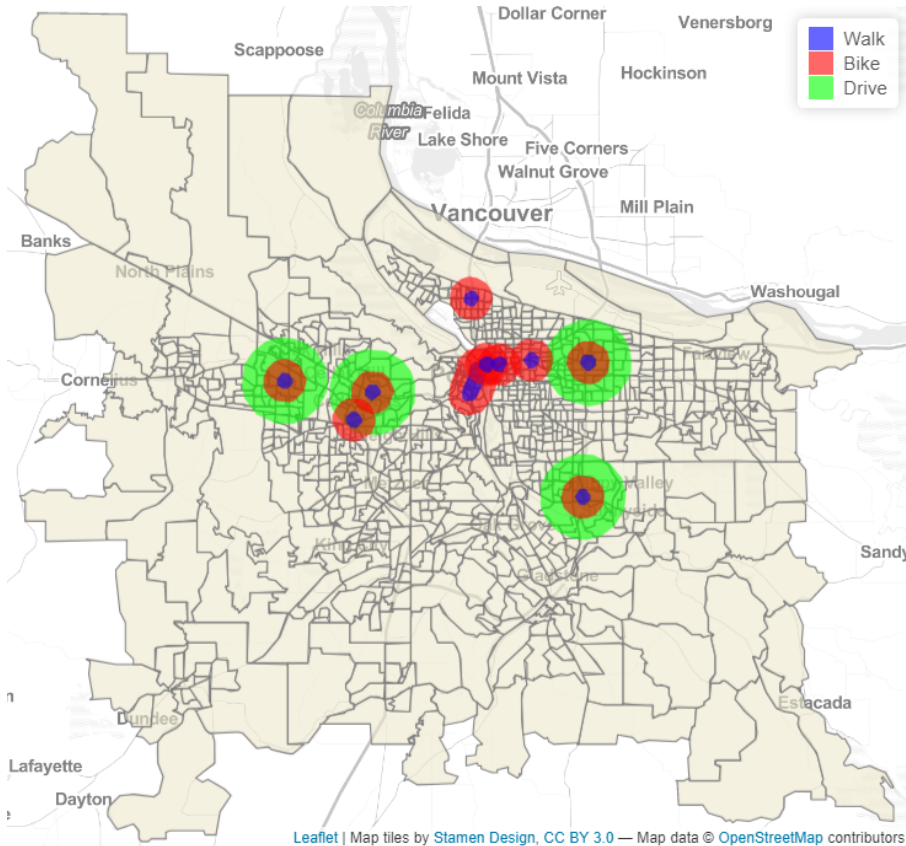

26 The reader should note that the bottom map contains the boundaries of US Census block  
27 groups (BG). BGs are statistical divisions of census tracts and generally defined to contain  
28 between 600 and 3,000 people. In addition, please note that driving buffers were not constructed  
29 for facilities without a PaR, i.e. without automobile parking. The close proximity of the transit  
30 mall facilities causes the overlapping modal buffers to appear as an oblong area covering the  
31 central portion of the city. Figure 6 illustrates how the different facility types (transit mall, TC,  
32 and PaR) generally serve spatially different regions of the metro area with the PaR serving  
33 suburban neighborhoods, the transit mall serving the downtown core, and the TCs primarily  
34 serving urban neighborhoods.

35 Table 2 displays the estimated population within the walking and biking modal buffers  
36 for the transit mall and TC facilities with the highest ridership (refer to Table 1). The high  
37 population density in the central city core results in more than double the estimated population  
38 within walking distance at some of the transit mall facilities compared to any of the TCs. The  
39 magnitude of differences is smaller when considering biking distance, however.

Rose Quarter Transit Center	2,352	23,886

4  
 5 The population within the walking, biking, and driving modal buffers is given in Table 3  
 6 for the four PaR facilities found within the top 20 locations by ridership. The population  
 7 estimates within walking and biking distances are generally lower for the PaRs than for the TCs,  
 8 owing to the lower population density in the suburban coverage areas. However, it appears that a  
 9 sizable population is estimated within the driving buffers and the suburban locations of potential  
 10 PaR locker sites could complement more centrally located locker sites on the transit mall or other  
 11 facilities with high ridership and/or equity priority in the urban core.  
 12

16  
 17

1 **Geographic coverage and convenience**

2 The distribution of population and employment activities throughout the region is an important  
3 element to consider when evaluating transit facilities as potential locker sites.

4 As shown in the map of Figure 7, the population density (per square mile) throughout the  
5 Portland region varies considerably with the highest densities occurring in the downtown area.  
6 More heavily populated areas tend to have smaller BGs as shown in Figure 7 since BGs contain  
7 between 600 and 3,000 people as previously mentioned.

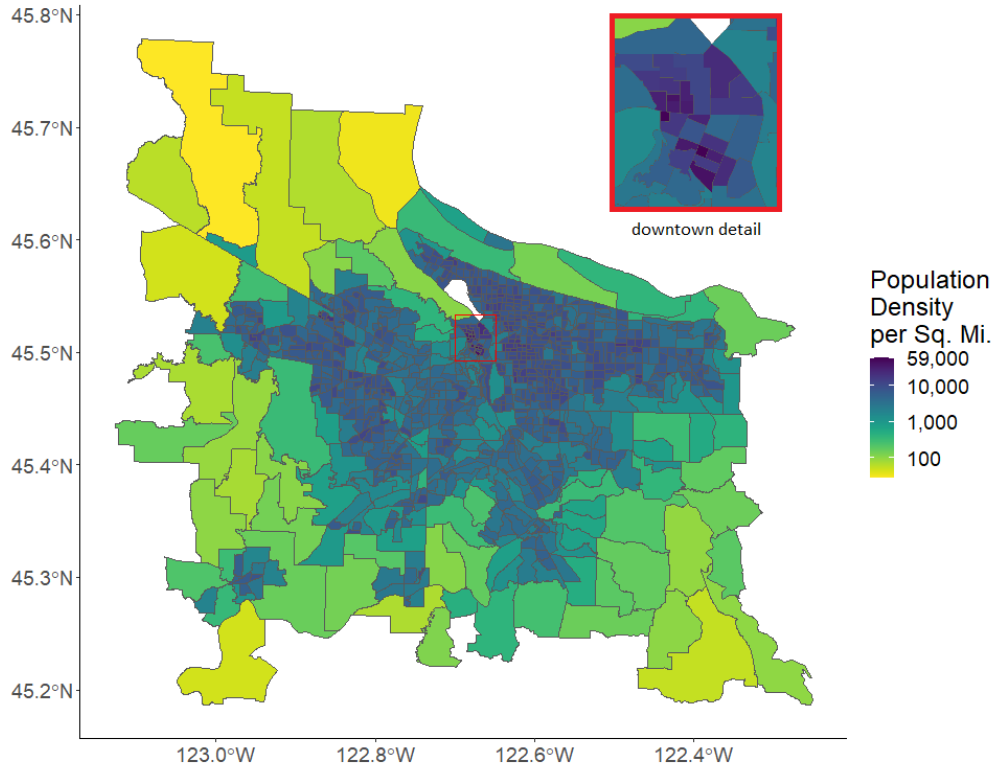

8 Similarly, the employment density (per square mile), calculated from the US Census  
9 Bureau's ZIP Codes Business Patterns data from 2018, is displayed by ZIP code tabulation area  
10 (ZCTA) in Figure 8. Again, the density is greatest in the downtown core. These high population  
11 and employment density areas generally correspond to the location of the transit mall.

12 Figure 7 and 8 should be compared against Figure 6 to understand the strong connection  
13 between population density, employment, and the location of high-ridership transit facilities.  
14 Though, it is also evident that focusing only on the top facilities by ridership provides a  
15 somewhat small coverage in the metropolitan region.

16 The distinction between employment and population areas is also relevant in terms of  
17 user convenience and trip origin and destination pairs. For example, a common carrier locker  
18 system located along the downtown transit mall may be accessible by the greatest number of  
19 people due to the high concentration of workers in the area, but it is not known whether this  
20 would directly translate to increased usage of the lockers. Workers who commute by public  
21 transit may find discomfort in transporting a package received at the origin of their commute  
22 home, particularly during peak hours when buses and trains are most crowded. These workers  
23 may find it more convenient to complete the transit portion of their commute first and retrieve  
24 their package from a locker located where they alight. Additionally, if the alighting stop were at  
25 a park and ride facility, the minimization of distance the package would need to be carried could  
26 encourage more usage of the locker services.

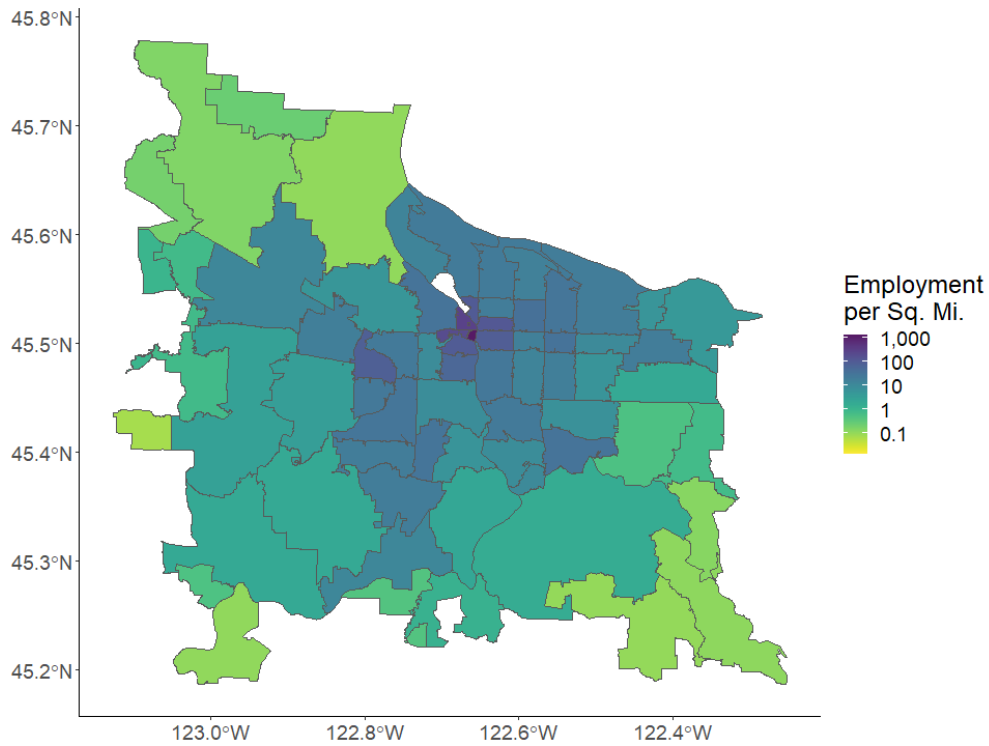

27

**Figure 8 Employment density by ZCTA in the Portland region**

1 **Sociodemographic equity metrics**

2 While there is no one prescribed method for evaluating equity, Litman (39) describes various  
3 methods and measures of evaluation and Di Ciommo and Shiftan (40) discuss criteria for  
4 differentiating population groups in equity analyses. Among those criteria include race or  
5 ethnicity, income, education level, and access to technology. These criteria are also highly  
6 relevant to study equity in terms of home deliveries (29).

7 For this equity analysis, demographic data for the TriMet service area was again sourced  
8 from the ACS 2018 5-year estimates (34) at the block group level and assumed to be uniformly  
9 distributed throughout the block groups. Demographic variables were chosen to represent the  
10 non-white population (any person who did not identify as “white only”), the population with  
11 lower education levels (high school degree, GED, or less), and the number households without a  
12 broadband internet subscription. The modal distances described in the previous section (Mode of  
13 transportation) were applied to the top 20 transit facilities by ridership and areal proportioning  
14 was used to calculate the demographic profiles within each modal buffer. Walking and biking  
15 buffers were applied to all top 20 transit facilities, but driving buffers were only applied to PaR  
16 facilities. The median household income corresponding to each facility was assessed based on  
17 the location of the transit facility as opposed to the buffer areas.

18 As this equity analysis is informational only and not meant as a final recommendation for  
19 site selection, and because of the vastly different attributes of the transit mall, facilities were  
20 evaluated within their respective types (PaR, TC, and transit mall) to elicit further discussion  
21 from stakeholders or policy makers.

22 A priority score was assigned to each facility by creating a method that utilized quintile  
23 breakpoints for the ridership and for each demographic variable and modal buffer combination.  
24 Once the quintile breakpoints were established for each group of facilities, a score of one through  
25 five was assigned to each facility for each variable and buffer distance combination. Higher  
26 scores were assigned for facilities with higher ridership, higher non-white or lower educated  
27 population, more households without broadband internet, and lower median income. Thus,  
28 higher scores indicated a greater equity priority. The scores for each variable were averaged and  
29 compared among the facilities with 1 being the lowest equity priority score and 5 the highest.

30 Results of the equity analysis for the PaR facilities in the top 20 locations by ridership are  
31 presented in Table 4. Of the four PaR facilities, the Gateway/NE 99th Ave Transit Center Park  
32 and Ride results in the highest equity priority score (= 3.6). The lowest equity priority score of  
33 the group (= 1.1) is assigned to the Sunset Transit Center Park and Ride which has the highest  
34 median household income and the lowest populations that are non-white, with low-educational  
35 attainment, and without broadband internet service.

36 Table 5 presents the equity results for the transit mall and TC facilities in the top 20  
37 locations by ridership. For facilities along the transit mall, the Pine—Pioneer Court segment on  
38 6th received a score of 4.0, the highest of the group with a low median household income and the  
39 highest populations that are non-white, with low-educational attainment, and without broadband  
40 internet service. Three additional segments, Pioneer Sq.—Madison on 6<sup>th</sup>, Oak—Pioneer Place  
41 on 5<sup>th</sup>, and Pioneer Place—Jefferson on 5<sup>th</sup> also received relatively high priority scores of 3.8.  
42 Since the locations along the transit mall are only a short distance from each other, there is  
43 considerable overlap in the modal buffer areas, leading to less variability among the  
44 demographic measures. The median household incomes associated with the transit mall facilities  
45 appear to be, on average, the lowest of the top 20 locations. However, it is important to mention  
46 that there is a high level of variability among incomes throughout the downtown core, as it is

1 home to both low-income and luxury housing, and the areas of the block groups are quite small  
 2 (less than 0.02 mi<sup>2</sup> in some cases) so one or two large, high-rise apartment buildings could  
 3 significantly alter the income metrics in a block group.

		Walk	Bike	Walk	Bike	Walk	Bike	
Beaverton Transit Center	\$36,857	740	3,970	893	4,890	274	1,295	3.8
Rose Quarter Transit Center	\$37,727	559	4,700	324	3,085	415	2,957	3.5
Hollywood/NE 42nd Ave Transit Center	\$45,284	682	4,125	420	2,637	379	1,356	2.8
Lloyd Center/NE 11th Ave MAX Station	\$59,107	574	4,385	251	2,808	292	2,069	2.5
N Lombard Transit Center	\$80,469	581	5,141	476	3,788	190	1,264	2.5

11 \*Scores were averaged without median household income.

1  
2 Out of the five TCs presented, the Beaverton Transit Center received the highest equity  
3 priority score of 3.8. The Lloyd Center/NE 11th Ave MAX Station and the N Lombard Transit  
4 Center both received scores of 2.5 – the lowest of the group – yet compared to the lowest scoring  
5 transit mall facility, these locations would appear to serve a less disadvantaged population.  
6

## 7 **FINAL DISCUSSION AND CONCLUSIONS**

8 Accessibility and equity approaches are presented for their complementary value. Transit  
9 data and American community survey data were gathered and processed to quantify and map  
10 several accessibility and equity metrics. The ridership evaluation identified transit facilities with  
11 high levels of potential locker users. The accessibility by mode was extended not only to study  
12 equity issues but also because most research on transit-oriented lockers assumes that the  
13 catchment area for transit riders is constrained by the distance they are willing to walk with a  
14 parcel. However, transit riders that drive their personal vehicle to park-and-rides will not be  
15 inhibited by “willing to walk” estimates, and similarly, those who access transit via bicycle are  
16 not best represented by “willing to walk” estimates.

17 Based on the data collected, a common carrier parcel locker system leveraging the transit  
18 mall ridership is reasonable based on ridership volumes; it offers consolidated parcel collection  
19 points at the densest area of the city’s employment and transit networks. Not only does the transit  
20 mall define the nexus of transit use, but the transit mall well-designed pedestrian facilities may  
21 even attract non-transit riders; workers may elect to take a mid-shift short walk to send or pick  
22 up parcels at transit mall facilities. The transit mall has also a high amount of foot traffic that  
23 provides a sense of safety for those retrieving potentially valuable parcels.

24 Locating common carrier parcel locker systems at suburban park and ride facilities not  
25 only improves spatial equity and coverage but also has the potential to serve a much greater  
26 population due to the convenience of personal vehicle access. Spatial constraints for locker  
27 placement and loading zones would be reduced or eliminated at many suburban locations. In  
28 addition, transit-users’ comfort preferences in transporting a parcel via bus or train are an  
29 important consideration for locating lockers at the origin or destination of the traveler. The  
30 transit mall is a transfer area and the origin of many return to home evening trips whereas the  
31 suburban locations may be preferable for users that would like to pickup a parcel after ending  
32 their transit journey.

33 The equity analysis uses demographic data from the area surrounding a transit facility to  
34 gauge which locations would be compatible with regional equity goals for development and  
35 investments. The results of the research show that there are complex tradeoffs between spatial  
36 coverage, type of facility, and equity metrics. Budget constraints are always present, though  
37 outside of the scope of this research, must be considered. Hence, the real-world application  
38 highlights equity and accessibility tradeoffs but it is not intended to determine final site  
39 selections that should include budget considerations and site design.

40 If a transit-based common carrier locker pilot is successfully adopted by consumers and  
41 delivery companies, there is potential to establish them at any transit facility with suitable space  
42 and qualifying demand. Like any reasonable pilot, a common carrier locker system could start  
43 with a smaller number of locations, and the equity analysis would ensure that the incremental  
44 growth of the locker program is cost efficient by reaching many users but also covering areas  
45 serving disadvantaged populations. Cities and transit agencies can be proactive in attracting  
46 public-private partnerships with interested delivery companies.

1           A future area of research includes locker site design, to incorporate the safety of parcel  
2 carriers during unloading as well as the security of consumers retrieving parcels. Other design-  
3 related research should ensure that the lockers are suitable for users of all ages and all abilities.  
4 On a macroscopic design scale, transit-oriented locker systems are relevant to ongoing  
5 conversations guiding the evolution of transit-oriented development. For this review, only the  
6 PaR facilities owned by TriMet were considered; other parking lots owned by local businesses  
7 and/or churches were not reviewed for ridership, equity, or parcel locker suitability but could be  
8 incorporated in a future study. Additionally, the impact delivery vehicle automatization on locker  
9 operations and design, VMT and carbon emission reductions, and an overall cost and benefit  
10 analysis of transit locker facilities would be interesting extensions of this research.  
11
