KEYWORDS: Reconstructability Analysis, Decomposition, Relations, Logic Functions, Many-Valued Logic.

ABSTRACT

A novel many-valued decomposition within the framework of lossless Reconstructability Analysis is presented. In previous work, Modified Reconstructability Analysis (MRA) was applied to Boolean functions, where it was shown that most Boolean functions not decomposable using conventional Reconstructability Analysis (CRA) are decomposable using MRA. Also, it was previously shown that whenever decomposition exists in both MRA and CRA, MRA yields simpler or equal complexity decompositions. In this paper, MRA is extended to many-valued logic functions, and logic structures that correspond to such decomposition are developed. It is shown that many-valued MRA can decompose many-valued functions when CRA fails to do so. Since real-life data are often many-valued, this new decomposition can be useful for machine learning and data mining. Many-valued MRA can also be applied for the decomposition of relations.

1 INTRODUCTION

One general method to understand complex systems is to decompose the system in terms of less complex sub-systems (Klir 1985, Krippendorff 1986). Full decomposition, as opposed to partial decomposition, consists of the determination of the minimal sub-sets of relations that describe the system acceptably. The quality of the decomposition is evaluated by calculating (1) the amount of information (or, conversely, the loss of information, or error) which exists in the decomposed system, and (2) the complexity of the decomposed system. The objective is to decompose the complex system (data) into the least complex and most informative (least error) model.

This paper is organized as follows: section 2 presents a background on Reconstructability Analysis, both conventional (CRA) and modified (MRA). Many-valued MRA decomposition is presented in section 3. Conclusions and future work are included in section 4.

2 RECONSTRUCTABILITY ANALYSIS

Reconstructability Analysis (RA) is a technique developed in the systems community to decompose relations or distributions involving qualitative variables (Conant 1981, Klir 1985, Krippendorff 1986, Zwick 1999). We are here concerned with lossless decomposition of completely specified set-theoretic (crisp possibilistic) functions and relations. (We do not address information-theoretic, i.e. probabilistic, distributions). In lossless RA decomposition, the aim is to obtain the simplest model of the data which has zero error. The models representing possible decompositions define a graph-based lattice of structures. A “model” is a structure applied to some data (here a set-theoretic relation). Each model is a set of sub-relations projected from the original relation and represented by look-up tables.

New lossless RA-based decomposition, called Modified RA (MRA) decomposition, has been introduced in (Al-Rabadi 2001, Al-Rabadi et al 2002). While CRA decomposes using all values of the function, MRA decomposes using (1) the minimum set of values from which the function can be reconstructed without error, and (2) the simplest model (at the lowest level in the lattice of structures) for each value in the minimal set.

The first principle is illustrated for Boolean functions as follows: For every structure in the lattice of structures, decompose the Boolean function for one value only, e.g. for value of “1”, into the simplest error-free decomposed structure. One thus obtains the I-MRA decomposition. This model consists of a set of projections which when intersected yield the original Boolean function. This is illustrated in the following example.
Example 1. For Boolean function:
\[ F = x_1x_2 + x_1x_3 \]

Figure 1 illustrates the simplest models obtained using CRA and MRA decompositions. While CRA decomposes for both “0” and “1” values of the Boolean function, MRA decomposes only for value “1”, since \( F(x_1,x_2,x_3) \) can be completely retrieved if one knows the \((x_1,x_2,x_3)\) values for which \( F = 1 \).

For Boolean functions there are two advantages of MRA over CRA: (1) MRA decomposition is simpler than CRA decomposition, so the MRA algorithm needs less time and space for its computation, and (2) MRA directly implements the intersection operation with an AND gate in binary logic; consequently MRA decomposition leads directly to a binary circuit and thus can be applied to both machine learning and binary circuit design. On the other hand, the intersection operation in CRA requires ternary logic to accommodate ‘don’t cares’ which are represented in top middle of Figure 1 by ‘-’. Therefore, CRA has no simple application in binary circuit design.

3 MANY-VALUED MODIFIED RECONSTRUCTABILITY ANALYSIS

This section presents MRA for many-valued functions and relations.

3.1 GENERAL APPROACH

Real-life data are in general many-valued. Consequently, if MRA can decompose relations between many-valued variables it can have practical applications in machine learning and data mining. Many-valued MRA is made up of two main steps which are common to two equivalent (intersection-based and union-based) algorithms: (1) partition the many-valued truth table into sub-tables, each contain only single functional value, and (2) Perform CRA on all sub-tables. Figure 2 illustrates the general pre-processing procedure for the two many-valued MRA algorithms, which will be explained in more detail below.

\[
\text{Original 3-valued table} \\
\begin{array}{c|c|c|c}
0 & 1 & 2 \\
\end{array}
\]

Step (1): Separate one-valued tables

\[
\begin{array}{c|c|c|c}
0 & 1 & 2 \\
\end{array}
\]

Step (2): CRA decompositions of all one-valued tables

\[
\text{Step (3): Application of MRA algorithm} \\
\text{Intersection Algorithm} \\
\text{Union Algorithm}
\]

Figure 2. Steps for many-valued MRA.

![Figure 1](https://via.placeholder.com/150)

Figure 1. Conventional versus Modified RA decompositions for the Boolean function: \( F = x_1x_2 + x_1x_3 \).
For an “n”-valued completely specified function one needs (n-1) values to define the function. We thus do all n decompositions and use for our MRA model the (n-1) simplest of these. For example, using the lattice-of-structures, decompose the 3-valued function for each individual value. One then obtains the simplest lossless MRA decomposition for value “0” of the function (denoted as the 0-MRA decomposition), for value “1” (1-MRA decomposition), and for value “2” (2-MRA decomposition). By selecting the simplest two models from these 0-MRA, 1-MRA, and 2-MRA decompositions, one can generate the complete function.

In the intersection method, first the CRA decompositions are expanded to include the full set of variable and function values, and these “expanded” decompositions are then intersected to yield the original table.

Equivalently, one can use a union operation to generate the corresponding many-valued MRA as follows: (1) Decompose the original table (function or relation) into sub-tables for each output value: e.g., \( T = T_0 \cup T_1 \cup T_2 \) for the corresponding output values \( O_0 \), \( O_1 \), and \( O_2 \) respectively, (2) Do the 3-valued CRA decomposition on each sub-table. Let \( M_i \) be the decomposition of \( T_i \). (3) The reconstructed function or relation \( (T^*) \) is the union of all the sub-table decompositions, \( T^* = \bigcup_{j=0}^{n-1} M_j \otimes O_j \), where \( \otimes \) is the set-theoretic Cartesian product. The union procedure can also be done with (n-1) decompositions.

### 3.2 COMPLETE EXAMPLES

Following are two examples which illustrate many-valued Modified Reconstructability Analysis of 3-valued functions. In the first example MRA can decompose the function for only two values, and one has no choice but to use both in the MRA model. In the second example, the function is decomposable for all three of its values, and the two simplest decompositions are chosen to define the model. In discussing the second example, we show that this approach is generalizable to set-theoretic relations, in addition to mappings.

**Example 2.** We will generate the MRA decomposition for the ternary function specified by the following ternary Marquand chart:

\[
\begin{array}{c|ccc}
X_3 & 0 & 1 & 2 \\
\hline
X_1X_2 & 0 & 1 & 2 \\
00 & 0 & 0 & 0 \\
01 & 1 & 1 & 0 \\
02 & 1 & 1 & 1 \\
10 & 0 & 0 & 2 \\
11 & 0 & 0 & 2 \\
12 & 1 & 1 & 1 \\
20 & 0 & 2 & 0 \\
21 & 1 & 1 & 0 \\
22 & 2 & 2 & 0 \\
\end{array}
\]

The following is the intersection algorithm for many-valued MRA for the ternary function in Example 2.

**Step 1:** decompose the ternary chart of the function into three separate tables each for a single function value. This will produce the following three sub-tables.

<table>
<thead>
<tr>
<th>Value “0”</th>
<th>Value “1”</th>
<th>Value “2”</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>010</td>
<td>102</td>
</tr>
<tr>
<td>001</td>
<td>011</td>
<td>112</td>
</tr>
<tr>
<td>002</td>
<td>020</td>
<td>201</td>
</tr>
<tr>
<td>012</td>
<td>021</td>
<td>220</td>
</tr>
<tr>
<td>100</td>
<td>022</td>
<td>221</td>
</tr>
<tr>
<td>101</td>
<td>120</td>
<td></td>
</tr>
<tr>
<td>110</td>
<td>121</td>
<td></td>
</tr>
<tr>
<td>111</td>
<td>122</td>
<td></td>
</tr>
<tr>
<td>200</td>
<td>210</td>
<td></td>
</tr>

<td>211</td>
<td></td>
</tr>
<tr>
<td>212</td>
<td></td>
<td></td>
</tr>
<tr>
<td>222</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Step 2:** Perform CRA for each sub-table.

**Step 2a:** The simplest error-free 0-MRA decomposition is the original “0”-subtable itself since it is not decomposable.

**Step 2b:** 1-MRA decomposition of D1 is as follows:
\section*{THE INTERSECTION ALGORITHM}

\textbf{Step 3.1:} Select the (3-1=2) simplest error-free decomposed models. In this example these are 1-MRA and 2-MRA decompositions. MRA thus gives the decomposition model of \(D_{11}:D_{12}:D_{21}:D_{22}\) from which the original function can be reconstructed as follows.

\textbf{Step 3.2:} Note that, for Tables 1 and 2, the MRA decomposition is for the value \(1\) of the logic function. Therefore, the existence of the tuples in the decomposed model implies that the function has value \(1\) for those tuples, and the non-existence of the tuples in the decomposed model implies that the function does not have value \(1\) but \(0\) or \(2\) for the non-appearing tuples. This is shown in Tables 1 and 2, respectively. Similarly note that, for Tables 3 and 4, the MRA decomposition is for the value \(2\) of the logic function. Therefore, the existence of the tuples in the decomposed model implies that the function has value \(2\) for those tuples, and the non-existence of the tuples in the decomposed model implies that the function does not have value \(2\) but \(0\) or \(1\) for the non-appearing tuples. This is shown in Tables 3 and 4, respectively.

\begin{table}[h]
\begin{tabular}{|c|c|c|c|}
\hline
\(X_1\) & \(X_2\) & \(X_2\) & \(X_3\) \\
\hline
0 & 1 & 1 & 0 \\
0 & 2 & 1 & 1 \\
1 & 2 & 2 & 0 \\
2 & 1 & 2 & 1 \\
2 & 2 & 1 & 2 \\
\hline
\end{tabular}
\end{table}

\begin{table}[h]
\begin{tabular}{|c|c|c|c|}
\hline
\(X_1\) & \(X_2\) & \(F_1\) & \(X_3\) & \(F_2\) \\
\hline
0 & 0 & 0,2 & 0 & 0,2 \\
0 & 1 & 1,0,2 & 0 & 1,0,2 \\
0 & 2 & 1,0,2 & 0 & 2,0,2 \\
1 & 0 & 0,2 & 1 & 0,1,0,2 \\
1 & 1 & 0,2 & 1 & 1,1,0,2 \\
1 & 2 & 1,0,2 & 1 & 2,0,1 \\
2 & 0 & 0,2 & 2 & 0,1,0,2 \\
2 & 1 & 1,0,2 & 2 & 1,0,2 \\
2 & 2 & 0,2 & 2 & 2,1,0,2 \\
\hline
\end{tabular}
\end{table}

\begin{table}[h]
\begin{tabular}{|c|c|c|c|}
\hline
\(X_1\) & \(X_2\) & \(F_1\) & \(X_3\) & \(F_2\) \\
\hline
0 & 0 & 0,0,2,0 & 0 & 0,0,1,0 \\
0 & 1 & 1,0,2,0 & 0 & 1,0,1,0 \\
0 & 2 & 1,0,2,0 & 0 & 2,0,1,0 \\
1 & 0 & 0,2,1,0 & 1 & 0,0,1,0 \\
1 & 1 & 0,2,1,0 & 1 & 1,0,1,0 \\
1 & 2 & 1,0,2,1 & 1 & 2,2,0,1 \\
2 & 0 & 0,2,2,0 & 2 & 0,2,1,0 \\
2 & 1 & 1,0,2,1 & 2 & 1,2,0,1 \\
2 & 2 & 0,2,2,1 & 2 & 2,0,1,0 \\
\hline
\end{tabular}
\end{table}

In Tables 1' and 2' (i.e., the decomposition for value \(1\) of the function), the existence of value \(1\) (of sub-relations \(F_1\) and \(F_2\)) means that the value \(1\) appeared in the original non-decomposed function for the corresponding tuples that appear in each table, but \textbf{does not imply} that the values \(0\) or \(2\) (of sub-relations \(F_1\) and \(F_2\)) did not exist in the original non-decomposed function for the same tuples. Therefore \(0\) and \(2\) are added to \(1\) as allowed values. In the remaining tuples, however, only \(0\) and \(2\) are allowed since the value \(1\) did not occur. Similarly, in Tables 3' and 4', the existence of the value \(2\) (of sub-relations \(F_3\) and \(F_4\)) means that the value \(2\) appeared in the original non-decomposed function for the corresponding tuples that appear in each table, but \textbf{does not imply} that values \(0\) or \(1\) did not exist in the original non-decomposed function for the same tuples. Therefore \(0\) and \(1\) are added to \(2\) as allowed values. In the remaining tuples, however, only \(0\) and \(1\) are allowed since the value \(2\) did not occur. Set-theoretically, obtaining tables 1', 2', 3', and 4' from tables 1, 2, 3, and 4 is described as follows:

\begin{enumerate}
\item Table 1': \((D_{11} \circlearrowright (0,1,2)) \cup (D_{11} \circlearrowright (0,2))\)
\item Table 2': \((D_{12} \circlearrowright (0,1,2)) \cup (D_{12} \circlearrowright (0,2))\)
\item Table 3': \((D_{21} \circlearrowright (0,1,2)) \cup (D_{21} \circlearrowright (0,1))\)
\item Table 4': \((D_{22} \circlearrowright (0,1,2)) \cup (D_{22} \circlearrowright (0,1))\)
\end{enumerate}

where \(\circlearrowright\) here means complement.

\textbf{Step 3.3:} Tables 1', 2', 3', and 4' are used to obtain the block diagram in Figure 3, where the following set-theoretic equations govern the outputs of the levels in the circuit shown in the figure:

\begin{align*}
F &= F_5 \cap F_6 \\
F_5 &= F_1 \cap F_2 \\
F_6 &= F_3 \cap F_4
\end{align*}
where $F_1$ is given by Table 1’, $F_2$ by Table 2’, $F_3$ by Table 3’, and $F_4$ by Table 4’, respectively.

**Step 3.1:** Using the decomposition model $D_{11}:D_{12}:D_{21}:D_{22}$ obtain $D_1$ and $D_2$ by standard methods as follows:

\[
D_1 = (D_{11} \otimes x_3) \cap (D_{12} \otimes x_1) \\
D_2 = (D_{21} \otimes x_2) \cap (D_{22} \otimes x_1) \\
D_0 = (D_1 \cup D_2)'
\]

where $D_1$ is the decomposition for function value “1”, $D_2$ for function value “2”, and $x_1$, $x_2$, and $x_3 \in \{0,1,2\}$.

**Step 3.2:** Perform the set-theoretic operations to obtain the total function from the decomposed sub-functions.

\[
x_1 x_2 x_3 F = (D_0 \otimes 0) \cup (D_1 \otimes 1) \cup (D_2 \otimes 2)
\]

Alternatively, one can use all three decompositions:

\[
x_1 x_2 x_3 F = (D_0 \otimes 0) \cup (D_1 \otimes 1) \cup (D_2 \otimes 2)
\]

The function value of $(x_1,x_2,x_3)$ is determined by the block diagram of Figure 4, where $G$ performs the following operation:

- $F = 0$ if $(x_1 x_2 x_3) \in D_0$
- $F = 1$ if $(x_1 x_2 x_3) \in D_1$
- $F = 2$ if $(x_1 x_2 x_3) \in D_2$

**Example 3.** Let us generate the MRA decomposition for the ternary function specified by the following ternary Marquand chart:
Utilizing the intersection-based algorithm, one obtains the following results for MRA for the ternary function in Example 3.

**Step 1:** decompose the ternary chart of the function into three separate tables each for a single function value. This will produce the following three sub-tables.

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>2</td>

<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>0</td>
</tr>
</tbody>
</table>

**Step 2:** Perform CRA for each sub-table.

**Step 2a:** The 0-MRA decomposition of D0 is as follows:

**Step 2b:** The 1-MRA decomposition of D1 is as follows:

**Step 2c:** The 2-MRA decomposition of D2 is as follows:

**THE INTERSECTION ALGORITHM**

**Step 3.1:** Select the two simplest decomposed models, namely the 1-MRA and 2-MRA decompositions. These are at a lower level in the lattice of structures than 0-MRA.

**Step 3.2:** Analogously to Example 2, one obtains the following expanded tables:

---

**Table 4**

<table>
<thead>
<tr>
<th>X₀X₁</th>
<th>X₃</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 0</td>
<td>0</td>
</tr>

<td>2</td>
</tr>
</tbody>
</table>

**D21**  **D22**
Step 3.3: Tables 4’, 5’, 6’, and 7’ are used to obtain the block diagram in Figure 5, where the following set-theoretic equations govern the outputs of the levels in the circuit shown in the figure:

\[
F = F_5 \cap F_6 \\
F_5 = F_1 \cap F_2 \\
F_6 = F_3 \cap F_4
\]

where F1 is given by Table 4’, F2 by Table 5’, F3 by Table 6’, and F4 by Table 7’, respectively.

\[
F = \begin{cases} 
0 & \text{if } (x_1 x_2 x_3) \in D_0 \\
1 & \text{if } (x_1 x_2 x_3) \in D_1 \\
2 & \text{if } (x_1 x_2 x_3) \in D_2
\end{cases}
\]

\[
F_5 = F_1 \cap F_2 \\
F_6 = F_3 \cap F_4
\]

THE UNION ALGORITHM

Steps 1 and 2 are the same as in the intersection algorithm.

Step 3.1: Using the decomposition model D01:D02:D11:D12:D21:D22 obtain D0, D1, and D2 by standard methods as follows:

\[
D_0 = (D01\otimes x_3) \cap (D02\otimes x_1) \cap (D03\otimes x_2) \\
D_1 = (D11\otimes x_3) \cap (D12\otimes x_1 x_2) \\
D_2 = (D21\otimes x_2) \cap (D22\otimes x_1)
\]

where D0 is the decomposition for function value “0”, D1 is for function value “1”, D2 for function value “2”, and x1, x2, and x3 ∈ \{0,1,2\}.

Step 3.2: Perform the set-theoretic operations to obtain the total function from the decomposed sub-functions. This can be done using only two of the three decompositions as in Step (3.2) of the union algorithm in Example 2, or alternatively, one can use all three decompositions as follows:

\[
x_1 x_2 x_3 F = (D0\otimes 0) \cup (D1\otimes 1) \cup (D2\otimes 2)
\]

The function value of \((x_1,x_2,x_3)\) is determined by the block diagram of Figure 6, where G performs the following operation:

\[
F = 0 \text{ if } (x_1 x_2 x_3) \in D_0 \\
F = 1 \text{ if } (x_1 x_2 x_3) \in D_1 \\
F = 2 \text{ if } (x_1 x_2 x_3) \in D_2
\]

Figure 6. Block diagram for the union algorithm of MRA of Example 3.

The logic function in Example 3 is decomposable using CRA with the lossless CRA model \(x_1 x_2 : x_2 x_3 \otimes x_1 x_3\). Consequently, unlike the previous example, both many-valued MRA and CRA decompose losslessly. Since both CRA and MRA decompose this function, we would like to be able to compare the complexities of the two decompositions. The complexity measure reported in (Al-Rabadi et al 2002) could be used, but needs to be extended to many-valued functions.
From the previous discussion, it follows that the extension of many-valued MRA from functions to relations is trivial. One just performs the union algorithm using all \( n \) decompositions, e.g., for three values \((D0\otimes0)\cup(D1\otimes1)\cup(D2\otimes2)\).

4 CONCLUSION

A novel many-valued decomposition within the framework of Reconstructability Analysis is presented. In previous work (Al-Rabadi 2001, Al-Rabadi et al 2002) Modified Reconstructability Analysis (MRA) was applied to Boolean functions. In this paper, MRA is extended to many-valued logic functions and relations. It has been shown that MRA can decompose many-valued functions when CRA fails to do so. Since real-life data are naturally many-valued, future work will apply many-valued MRA to real-life data for machine learning, data mining, and data analysis.
